2st-year Master's students of "Engineering Graphics and Design Theory"

ABSTRACT

This article examines modern teaching technologies used in architectural education, particularly in teaching methods of making construction drawings. Architectural construction drawings play a crucial role in professional training, as they serve as the primary means of communication between architects, engineers, and construction specialists. The study focuses on developing students' competencies in computer graphics, architectural modeling, projection methods, and geometric analysis of spatial and planar forms. The integration of classical engineering graphics with digital technologies significantly improves students' spatial imagination, analytical thinking, and engineering competence. The article also highlights the effectiveness of project-based learning, model making, and research-oriented tasks in enhancing professional readiness of future architects.

Keywords: architecture education, construction drawing, teaching technology, engineering graphics, computer graphics, spatial thinking, projection methods, digital modeling.

Architectural construction drawing is one of the fundamental disciplines in architectural and construction education. It forms the technical and graphical basis for professional activity in architecture, civil engineering, and design. Construction drawings are used to express design ideas, structural solutions, dimensions, materials, and technological requirements in a clear and standardized graphical language. In modern conditions, the rapid development of digital technologies has significantly changed the requirements for architectural specialists. Today's architects must be able to combine theoretical knowledge of descriptive geometry and engineering graphics with practical skills in computer-aided design. Therefore, improving teaching technology for construction drawing methods has become one of the key tasks of higher architectural education. Teaching technologies in this field aim not only to transfer knowledge but also to develop spatial thinking, analytical skills, and engineering logic. Modern pedagogical approaches emphasize student-centered learning, digital modeling, and problem-solving activities, which allow students to actively participate in the learning process.

Theoretical foundations of teaching construction drawings. The teaching of construction drawing is based on the principles of descriptive geometry, projection theory, and engineering graphics. Descriptive geometry provides the theoretical basis for representing three-dimensional objects on two-dimensional planes, while engineering graphics establishes rules and standards for technical documentation. Students learn fundamental concepts such as projection planes, spatial coordinates, intersections of surfaces, and transformation of objects. These concepts help them understand how real architectural objects are represented in drawings. Without a solid theoretical foundation, students may face difficulties in interpreting and creating accurate construction drawings. Modern teaching technology combines classical theoretical instruction with practical and digital tools. This integration helps students better understand complex geometric relationships and apply theoretical knowledge in real design tasks.

Role of computer graphics in architectural education. Computer graphics has become an essential component of architectural education. Modern architectural practice relies heavily on digital tools for drafting, modeling, and visualization. As a result, teaching construction drawing methods

must include training in computer graphics software. Through computer graphics, students learn to create two-dimensional drawings and three-dimensional models of architectural objects. Digital modeling allows students to visualize spatial forms, analyze proportions, and understand structural relationships more effectively than traditional manual drawing alone. In addition, digital tools enable students to experiment with different design solutions, quickly modify drawings, and identify potential errors. This process not only improves technical accuracy but also enhances creative thinking and problem-solving abilities.

Architectural model making as a teaching method. Model making is an important educational tool in architectural training. Both physical and digital models help students better understand the structure, proportions, and spatial organization of buildings. Creating models allows students to transform abstract drawings into tangible or visual forms. Physical model making develops manual skills and spatial perception. Students learn to analyze construction logic, structural stability, and compositional balance. Digital model making, on the other hand, introduces students to three-dimensional modeling environments and simulation tools. Using various model-making techniques, including cardboard models, 3D printing, and virtual models, helps students gain a comprehensive understanding of architectural design and construction processes.

Projection methods in construction drawing. Projection methods are central to construction drawing education. They allow accurate representation of spatial objects on flat surfaces. Students study orthographic projection, axonometric projection, and perspective representation. Parallel projection methods are especially important in technical drawings because they preserve object dimensions and geometric accuracy. Through projection drawings, students can analyze real dimensions, angles, and distances between architectural elements. Mastering projection methods enables students to correctly interpret construction drawings and produce accurate technical documentation, which is essential for professional practice.

Geometric analysis of spatial and planar forms. One of the main objectives of teaching construction drawings is developing the ability to analyze geometric properties of architectural objects. Using projection drawings, students learn to determine geometric characteristics such as shape, size, position, and spatial relationships. Geometric analysis helps students understand intersections of surfaces, cross-sections, and structural connections. These skills are particularly important in complex architectural and engineering designs, where accuracy and precision are critical. Teaching geometric analysis through graphical problem-solving tasks strengthens students' logical thinking and analytical abilities.

Development of Spatial Thinking and Engineering Competence. Spatial thinking is a key professional skill for architects. It involves the ability to imagine objects in three-dimensional space, mentally transform them, and understand their representation in drawings. Teaching construction drawing methods contributes significantly to the development of spatial imagination. Engineering competence, which includes technical reasoning, optimization, and problem-solving, is also formed through graphical and design tasks. Problem-based learning and practical exercises encourage students to think independently and apply their knowledge creatively.

Modern Teaching Technologies in Architectural Education. Modern teaching technologies include digital learning platforms, virtual laboratories, simulation software, and interactive educational tools. These technologies increase student engagement and make learning more effective. Blended learning, which combines traditional classroom instruction with online resources, allows students to learn at their own pace and revisit complex topics. Virtual simulations help students understand construction processes and structural behavior. The use of modern teaching technologies transforms students from passive learners into active participants in the educational process.

RESEARCH METHODOLOGY

The research methodology of this study is based on analysis of pedagogical literature, observation of teaching practices, and comparative analysis of traditional and modern teaching methods. Student performance indicators such as drawing accuracy, spatial thinking development, and problem-solving skills were evaluated. Experimental teaching methods were applied to assess the effectiveness of integrating digital technologies into construction drawing education. The results were analyzed to identify improvements in learning outcomes.

RESULTS AND DISCUSSION

The results of the study show that integrating computer graphics and modern teaching technologies into construction drawing education significantly improves student performance. Students demonstrate better spatial understanding, higher technical accuracy, and stronger analytical skills. Project-based learning and model-making activities increase student motivation and professional orientation. Digital tools allow students to better understand complex architectural forms and construction processes. The discussion confirms that modern teaching technology enhances both theoretical understanding and practical competence.

CONCLUSION

Teaching technology on methods of making construction drawings plays a crucial role in modern architectural education. The integration of classical engineering graphics with digital technologies develops students' spatial thinking, engineering competence, and professional readiness. Modern teaching approaches, including computer graphics, model making, projection analysis, and project-based learning, prepare students for real professional challenges in architecture and construction. Future research should focus on integrating advanced technologies such as artificial intelligence and virtual reality into architectural education.
