Annotation. This article provides information on the specific features of media competence in teaching biology and physics, increasing students' interest in education, developing new interactive teaching tools, and using them effectively.

Keywords: inclusive education, digitization, media competence, multidisciplinary, online platforms, creativity and innovation, multimedia.

Introduction. The decree on approving the Concept for the Development of the Education System of the Republic of Uzbekistan until 2030 aims to modernize the national education system and implement advanced pedagogical approaches.[1]

One of the main goals and directions of the decree is the digitalization of the education system: the new concept includes the digital transformation of the education system, which involves the broad implementation of information technologies. This aims to increase students' interest in education, develop new interactive teaching tools, and use them effectively.

Inclusive Education: Our research contributes to tasks such as ensuring equal conditions for all students in the education system and developing educational programs that cater to the diverse needs of students.

Materials and Methods: The integration of biology and physics plays an important role in demonstrating the interconnection of natural sciences to students and enhancing their media competence. Media competence is the ability of students to effectively use information technologies, search for, analyze, interpret information, and apply it in various contexts. The specific features of media competence in integrating biology and physics education may include the following (see Table 1).

Table 1.

Mediakompetence Levels and Features

O/n	Levels	Content of the Levels
1	Development of the Ability to Search and Analyze Information:	Through the integration of biology and physics, students learn to analyze information related to various subjects. For example, in explaining biological processes, the basic laws of physics, such as the conservation of energy and changes in temperature, can be applied to illustrate physical phenomena.
2	Application of Information Technologies:	To enhance media competence in biology and physics, it is important to effectively use modern information technologies (computer programs, simulations, scientific laboratory tools,

		video materials). For example, in explaining biological systems, students can visually study biological processes through 3D models or simulations. In physics, various experiments and experiment simulations can be explored through online resources.
3	Development of a Multidisciplinary Approach:	To demonstrate that biology and physics are interconnected subjects, teachers with media competence can organize lessons by combining various educational resources. For example, in studying the process of photosynthesis in plants in biology, the concepts of light and energy from physics can be applied together, helping students develop scientific thinking skills.
4	Application of Electrical Engineering and Computer Simulations:	Increasing media competence also involves technological approaches between biology and physics. For example, in biological research, data obtained through laboratory instruments and sensors can be analyzed on a computer. In conducting various technical experiments in physics and biology, the development of media competence allows students to manage scientific processes and accurately analyze measurements.
5	Development of Collaboration and Communication Skills:	In teaching biology and physics, it is crucial to encourage students to work together, exchange ideas, and integrate various scientific information. Media competence helps students participate in scientific discussions, present acquired data visually, and develop skills in creating videos, infographics, or slides.
6	Application of Innovative Pedagogical Methods:	In teaching biology and physics, teachers with media competence can increase students' interest by applying new pedagogical methods (such as flipped classrooms, gamification, online learning platforms). Students can learn biological and physical processes through various interactive materials, games, or virtual laboratories.
7	Encouraging Students to Self-Assess and Reflect:	Media competence helps students assess their knowledge and supports self-development. In biology and physics, students can strengthen their knowledge through various tests, interactive tasks, and online assessment tools. This enhances their ability to learn independently.

Analysis and Conclusion: Practical biology lessons play a key role in developing media competence, as they not only enhance students' biological knowledge but also improve their skills in effectively using modern information technologies. By independently inputting parameters and making the lesson dynamic and interactive, students achieve several positive outcomes:

Information Search and Analysis: In practical biology lessons, students use the internet and various information sources to find the necessary data for experiments and observations. This process enhances their media competence, as they develop skills in identifying information sources, analyzing them, and selecting relevant data.

Application of Innovative Technologies: To make the lessons more dynamic, students can use modern technologies such as simulations, software, or online platforms. This not only helps reinforce knowledge in the field of biology but also
develops media competence, as students acquire skills in creating and using technologies in various situations.

Developing Creative and Innovative Ideas: Students develop innovative and new ideas by selecting the parameters for their experiments and observations. Through applying their acquired knowledge in practice and creating new methods, they enhance creative thinking. This process is a part of media competence, providing students with the opportunity to successfully apply their knowledge in both personal and social contexts.

Using Multimedia Tools: Students can use multimedia tools to make biology practical lessons more dynamic and visual. These tools can be applied to illustrate biological processes, present results, and facilitate discussions. This enhances students' media competence, as they develop skills in creating and using various multimedia tools (see Figure 1).

Figure 1. Media Competence in Practical Lessons

Thus, by developing media competence in practical biology lessons, students not only enhance their biological knowledge but also improve their ability to effectively use information technologies and develop creative thinking skills. This enables them to acquire all the competencies necessary to succeed in the modern world.
