Abstract

This article provides detailed information about the technique of running for medium and long distances, the preparation process and important factors for achieving success. Running is one of the most natural human movements, and it is one of the main types of sports. Running for medium and long distances is a complex sport that requires physical training, correct technique and breathing.

Keywords: running for medium and long distances, running technique, preparation process, achieving success, achieving success, sport, physical training, correct technique, breathing, body structure, weight.

Introduction. Correct execution of running technique is the main factor for achieving high results in all types of running. It is known that the technique of running for medium and long distances, according to its external signs, should be expressed in the ability to run smoothly and beautifully, and the correspondence of the alternation of the rhythm of running, such as muscle tension or relaxation, should be such that all movements along a straight line are coordinated.

Individual features of the body structure, of course, affect the running technique, which indicates that each athlete has his own unique way of mastering the running technique. As a result of long training, quite stable skills can be formed, including incorrect movements that become a habit. As a result, the athlete may perform the running technique incorrectly, and in this case, spending too much energy and time on running will affect the sports result. Therefore, it is advisable to pay attention to teaching the correct running movements from the initial stage of training in running.

When comparing and analyzing the technique of runners of different sports categories, it is necessary to proceed from the characteristics of their running style.

Usually, when analyzing the running technique, the second step or cycle of movement is defined as a unit of movement. Each cycle consists of two periods of support and two phases of flight. During running, the duration of the support period in the movement of the legs is always shorter than the duration of the period of swinging movements, thus the flight phase occurs.

When an athlete runs, the following features of the influence of external forces are observed: a) overcoming the inertia of a stationary position when running from the start; b) changing the resistance force of the environment depending on the running speed; c) the periodicity of the effect of the support reaction.

During the support period, the pressure force exerted on the ground and the sharp increase in the reaction of the support, which exceeds the weight of the runner, cause vertical oscillations of the total center of gravity of the body. This oscillation, although not very noticeable, has its effect on the violation of the running technique.

Movements in the joints are carried out along large arcs and at the required speed. Therefore, the effect of inertia and the interaction of muscle activity are fully manifested during running.

In the modern technique of running, a softer foot placement is required at the initial support, and for depreciation, the foot is usually pressed to the front of the palm, closer to the line of the general center of gravity of the body. The placement of the leg, slightly bent at the knee joint, in the initial phase of the support depends on the running speed. As the running speed increases, the foot is placed on the ground more tensely than in the general case, and the support reaction time becomes shorter.

In order to prevent large vertical oscillations during depreciation, the push-off at an acute angle is carried out by bending the supporting leg at the knee and ankle-foot joints. The more the ankle joint is bent, the faster the runner's movement will be, because in this case the push-off occurs at a sharper angle. The leg should not be bent too much at the knee joint, as this will further lower the overall center of gravity, which will make the push-off dynamics much more difficult, and of course, will slow down the running speed.

A distinctive feature of the running technique of highly qualified athletes is the complete or almost complete fixation of the supporting leg in all joints, especially in the ankle-foot joint. In this case, the swing leg plays a significant role in the rapid upward and forward movement of the thigh, depending on the running speed. It is known that with an increase in the amplitude of the swing leg, the pressure exerted by the supporting leg on the ground also increases, which means that with an increase in the push force, the running speed increases.

Correct posture during running. Maintaining stability during running is an important element of the technique. We know that running changes the body's balance with each step. Therefore, movements should be carried out with the correct posture of the body and the constant position of the head.

The correct (specific to each runner) posture of the body creates the necessary conditions for the functioning of muscles and internal organs. In middle and long-distance running, the body angle fluctuates between 70°-80°. In this case, it is easier to maintain the natural length of the stride. Excessive angle shortens the stride length and creates the so-called “falling run”, in which the landing is rough and heavy, the shin of the swinging leg is more backward, and it is difficult to raise the thigh forward in time. On the contrary, an excessively straight body position leads to a backward shift of the shoulders, which, as a rule, increases the vertical oscillations of the hip joint. Running in this case takes on the appearance of “playing” or running sideways, which cannot be called correct.

The angle of the body angle should be optimal, based on the running speed. Only then can various aspects that violate the running technique be avoided. In this case, running is expressed in the necessary balance, comfortable rhythm, alternating muscle relaxation and tension. These are the main signs of a rational technique. When running, the head is kept straight, the gaze should be fixed 8-10 m ahead. This helps to maintain balance during running and control the degree of body deflection when the running speed increases. The activity of the hands should correspond to the acquired rhythm of running and correspond to the light rotation of the body around the vertical axis. The position of the hands (high, low) should be varied, comfortable for the runner himself, he should move without straining the upper shoulder girdle.

The main factor in the technical skill of a runner is his physical qualities (strength, speed, endurance). Physical qualities should be continuously improved in parallel with technical skill. At the same time, it should be said that, unlike the best foreign runners, many of our runners perform some stages of movement quite roughly, without sufficient relaxation at the stage of placing the foot on the front support, tense position of the torso, head, arms, jerking movements. In our opinion, the so-called gymnastic method in the process of teaching running technique, that is, teaching running movements using running and jumping gymnastics, may not always be beneficial. When teaching hands to run,

performing hand movements looking at the mirror helps a lot in mastering running technique. It is precisely due to the large number of jumping and running exercises in the training process that strength features appeared in the running technique of our athletes, which, albeit slightly, affects their natural movement.

We are not against the use of running and jumping gymnastics as an additional tool in teaching running technique, but it is also impossible to accept it as the main one. Running and jumping gymnastics should serve as an additional means of eliminating errors in running technique, but it is recommended to apply selected exercises to them, based on the characteristics of the defects in the technique of each individual runner. The best tool for teaching the perfect running technique is, of course, running at low speed. According to the literature, in the 1970s and 1980s, Arthur Lydiard, the world's strongest coach, offered his students frequent and long runs at low speed, thereby solving two important tasks: firstly, developing general endurance, and secondly, forming the correct skills in teaching running technique. In this case, it is very important to pay attention to the correct posture - the running position and the ability to control the overall center of gravity deviation when changing running speed. This helps the body parts to create the necessary balance during running and relieves the runner from excessive compensatory movements that usually lead to tension in individual muscle groups that are not directly involved in running.

Thus, it is appropriate to mention the following as the main means of training and improving running technique:

1. Running at a slow pace, controlling your movements.
2. Running with a gradual increase in speed (acceleration).
3. Using certain exercises from running and jumping gymnastics, which are selected based on the shortcomings in the running technique of each individual runner.
4. It is recommended to use imitation exercises.
5. Use auxiliary exercises in a timely manner.
6. Pay attention to the correct execution of arm and leg movements during running.
7. It is necessary to constantly perform jumping exercises.
