Primary school teacher, 5th general education school

Abstract: The article describes the logical thinking skills of first graders . For them , logical thinking , solving problems and It is an important tool for analyzing news . It helps students with logical thinking to understand complex concepts , express their thoughts clearly and solve problems consistently .

Key words : Logic , thought , thinking , reasoning , logic , reality , research , development , consistency , simulation , understanding , English , etc.

Today, the abundance of information in the development of students' thinking requires primary school students to extract important and useful information through logical thinking. This process is of great importance.

Logic is not only the ability to think, but also to reason consistently and correctly, and to find the right solution to a given problem or problem. That is, it is understood as the ability of people to think usefully, clearly, reasonably, or logically in their daily activities and relationships.

Logical thinking is one of the highest levels of thinking, reflecting an important aspect of a person's creative activity, and it means the connection of thoughts based on sequence and consistency. Thus, logical thinking means the way in which a person thinks about things , realities or impressions that he sees , hears, knows, feels and understands in a way that is understandable to others.

Logic is the process of applying the laws of thought in written and oral speech. Methods for developing logical thinking include solving and completing logical games, puzzles, problems, and riddles, playing chess, reading books, learning critical thinking, participating in discussions and debates, imagining the thinking process, simulating situations, keeping a diary, and others. In this process, it is possible to develop logical thinking by paying close attention to each element, searching for unrelated or ambiguous aspects between different objects, and identifying and comparing new facts. In the educational process, the use of tasks aimed at developing logical thinking often requires the use of project methods, research methods, programming, and problem-based learning methods.

There are several ways to determine logical thinking:

First, it is a complex cognitive process aimed at mastering the world through thought;

The second is to constantly seek out and discover new things and innovations.

Thinking is a process that begins when a person is faced with a problem and requires a deeper thought to come up with a solution. We will consider issues that encourage logical thinking,

For example: There were 6 birds on a tree branch . 2 of them flew away? Two converse problems can be formulated for this problem.

1) There were several birds on a tree branch. After 2 birds flew away, 4 birds remained on the tree branch. How many birds remained on the tree branch?

2) There were 6 birds perched on a tree branch, and after a few flew away, only 2 birds remained. How many birds flew away?

VOLUME-5, ISSUE-3

A direct statement is distinguished from a simple statement.

Problem 1. There are 8 apples in one box, 5 more than in the second box. How many apples are there in the second box? Solution: 8-5=3 (apples)

Answer : 3 in the second box I ca n't .

Problem 2. Vali drew 6 rabbits . Vali drew 2 more rabbits than Zakir drew. How many rabbits did Zakir draw ? Solution: 6-2=4. Answer: Zakir drew 4 rabbits. Simple problems on addition and remainder .

Problem 3. Ahmad drew 3 dolls and two balls. How many toys did Ahmad draw? Solution: 3+2=5. Answer: Ahmad drew 5 toys.

Problem 4. Zakir picked 7 apples from the apple tree and ate 3. How many apples does Zakir have left? Solution: 7-3=4 (apples). Answer: Zakir has 4 apples left.

Problem 5 There were 4 red pens on the table and 4 blue pens were added to them. How many pens were there on the table: Solution: 4+4=8 Answer: There were 8 pens on the table.

Another type of simple problem is one that asks how many units to increase or decrease a number by.

1. Ahmad has 6 pens, Salim has 2 more than him. How many pens does Salim have? Solution: 6+2=8 (pencils) Answer:

Salim has 8 pencils. Salim drew 4 red cars and Ahmed drew 3 green cars. How many cars did they both draw? Solution: 4+3=7. Answer: Both of them drew 7 cars.

It is possible to solve text problems First of all , the formation of advanced thematic concepts along with the acquisition of basic knowledge specified in their program It plays an important role in developing students ' thinking skills . For example : If we want to form a correct understanding of addition in students, it is necessary for children to solve a sufficient number of simple problems on finding the sum of almost all sets by performing the operation of combining sets. For example: The following problem is given. Ahmed has 6 colored pencils and three ordinary pencils. How many pens does Ahmed have in total? To solve this, first take 6 pens and then add 3 more pens, and count how many pens there are in total. Then, to solve the problem, it is necessary to add 6 to 3 and explain that the resulting number, 9, is the sum of these two numbers.

So By solving many similar problems , he slowly learns the concepts of growth and understands the importance of combining them into a generalization . For example: when solving a problem about finding an unknown component of an operation, students try to isolate the connection between the components of arithmetic operations and the results and apply it to solving problems. Problems are concrete material, with their help students develop new knowledge and learn to perform thinking operations in the process of solving them.

Here is a summary of the 1st grade mathematics course : 1. 8 lessons in the first grade , 2 lessons in the second grade o r t i c a n o r b o r. How many pomegranates are in the second plate? There are 8 pomegranates in the 1st plate, 2 more in the 2nd. Solution: 8+2=10. Answer: There are 10 pomegranates in the second plate. 2. There is 10 liters of cotton oil in one can, and 3 liters less in the second. How many liters of cotton oil are in the second can? In the 1st can — 10 liters In the 2nd can - ? -3 liters less. Solution: 10-3=7 liters Answer; There are 7 liters of cotton oil in the second can. 3. There are 10 students in the schoolyard, 4 of whom are girls. How many of them are boys? Boys? Total - 10. Girls - 4 Solution: 10-4=6. Answer: Six of them are boys. Existing knowledge and thinking skills are strengthened through application.

VOLUME-5, ISSUE-3

The presence of concrete material in the formulation of problems allows the integration of theory and practice. When solving problems, the student becomes convinced that many mathematical concepts have their roots in the experience of people in real life. Through solving problems, they become familiar with information that is important in the field of knowledge and experience. For example, the content of many problems solved in elementary grades includes the achievements of children and adults in the national economy, technology, sports and culture of our country. The process of solving problems itself, with certain methods, has a positive effect on the intellectual development of students, because it requires mental operations: analysis and synthesis, clarification, comparison, generalization. For example: the student analyzes when solving any problem. Separates the question from the problem conditions. Synthesizes when developing a solution plan, in this case he uses clarification, as a result of solving problems of the same type many times, the student generalizes knowledge about the connections between the numbers given in this type of problem and the numbers being searched.

To introduce students to simple problems. The first arithmetic problems that students are introduced to should be understandable, including problems with sums and remainders. It is appropriate to introduce students to the solution of such problems by parallel deduction, and such problems include the following.

1. Ahmad drew 3 dolls and 2 footballs. How many toys did Ahmad draw? 2. Bahadir picked 6 cucumbers from a pile and took 2 cucumbers. How many cucumbers were left? The second type of simple problems in terms of difficulty is problems about increasing or decreasing this number by a certain number of units. We will give examples of such problems. 1. Zokir has 6 notebooks, but Ahmad has 2 more than him. How many notebooks does Ahmad have? Solution: 6+2=8. Answer: Ahmad has 8 notebooks. 2. Maysara read 7 fairy tales, but Gozal read 3 fewer fairy tales. How many fairy tales did Gozal read? Solution: 7-3=4 Answer: Gozal read 4 fairy tales.
