METHODOLOGY FOR TEACHING ELEMENTARY STUDENTS TO SOLVE ISSUES OF SPEED, TIME AND DISTANCE

Sharipova Mehrinoz Erkinovna,
2nd year master's degree from Tashkent Chemical International University

Annotation: This article describes the scientific information and scientific observations of the method of teaching speed, time and distance problems in the elementary school mathematics textbook, and discusses what the student will enjoy about practical mathematics.

Key words: speed, time and distance, equation, theory, scientific and theoretical observation, students' awareness of mathematical concepts, high intelligence.

Mathematics has wide potential as a learning discipline in maturing the growing younger generation. He develops the thinking of the reader, regrets their intelligence, regulates it, goes to form in the readers the qualities of goal orientation, logical thinking, resourcefulness. At the same time, the correct, conscious approach of contemplation is brought up, making them tasteful, with the need for beauty.

In the current rapidly changing world, when preparing our young people for life, it will be necessary to educate them with the characteristics that they will be able to find the optimal solution to the problems unexpectedly posed to the individual and the team, independently seek the necessary information and extract the necessary ones from them based on analysis, communicate with all, apply It is known that now a person lives in the world of information. To achieve success both in reading and in everyday activities, it is necessary to have the necessary information, to track them down, to learn how to track down and use the necessary one. In addition, in an educational institution, students must be able to explain their opinion to others, be able to understand them by listening to others, enter into an argument that is, in other words, prepare them in such a way that they have communicative competence. Together with this, it is necessary to form that they can use the learned knowledge, skills and skills to solve the problems found in their daily lives. Accordingly, these tasks should be prepared in an educational institution so that students can apply them in their vital needs, in conjunction with the acquisition of the necessary knowledge, skills and abilities in the process of studying educational subjects.

In the methodology of teaching mathematics, issues related to movement include issues related to finding links between the three quantities that characterize movement – speed , time and distance, in which the quantities mentioned participate as directed quantities. In general, the following issues are included in the action:

a) simple and complex issues related to the movement of one body, in these issues one of the quantities – speed, time or distance-participates in depending on the other two;

(B) issues of meeting Action;

v) issues regarding the actions of two bodies in the opposite direction;

g) issues regarding the unidirectional movement of two bodies (this type of issue is not considered in primary school).

It is known that in order for the reader to learn a complex solution, it is necessary to first find out the solution of simple issues. For this reason, it is necessary to start working on issues related to the movement by solving simple issues. But before getting into the action on simple issues, it is necessary

to solve a number of issues related to determining the distance, determining the time interval. The solution of these issues should be associated with the transition of program materials of the I – II Class. for example, before introducing children to units of length measurement (centimeters, decimeters, and meters), they should be trained in solving issues related to distance determination. We give examples of such issues.

The teacher will install a cardboard model of the car on the board, in which he will mark the departure point in advance. Then the teacher begins to push the model and stops it after a certain time interval has passed.

How far has the car passed? (One meter, more than a meter, less than a meter). Students, led by a teacher, measure the distance from the teacher's desk to the wall, and then to the wall on the opposite side. Let's say that the numbers 5 m and 2 m are formed*. This issue is drawn up: "the distance from the wall to the table is 5 m, and from the table to the second wall is 2 m. Find the distance from one wall to the other".

Resolution: 5 + 2 = 7 (m).

During the period of teaching the topic" clock, minute " (2nd grade), it is advisable to give such issues to children:

The student left the house at 8-u 30 minutes and reached school at 8-u 50 minutes. How many minutes are the reader on the road?

In the morning he set out from the village towards the town at the same time on horseback and foot. The cavalry arrived in the city at 12 AM during the day and the infantry at 3 pm during the day. Which of these had a lot of time on the road and how many days?

Students should be taught to summarize their perception of movement and perform appropriate drawings after solving such issues. For this purpose, it is necessary to observe the movement of one object and the movement of two objects relative to each other. for example, one body (bus, car, person, etc. k.) can move quickly and slowly, stop. Two objects can move towards each other and, as a result, approach each other, moving in the opposite direction (in which they move away from each other), moving in the same direction. Observing all this in class conditions, it is necessary to indicate how the corresponding drawings will be drawn: it is accepted to mark the path with an incision, the place of departure (point), the place of arrival with a point in the incision and the corresponding letter or with a hyphen. The meeting place is indicated by a flag, the direction of movement is indicated by an arrow. For example, a meeting action is defined.

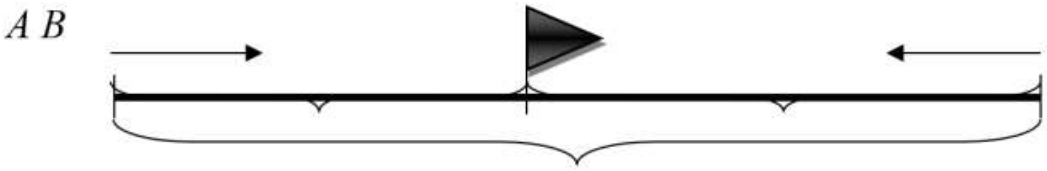

AB denotes the path that cross objects must pass through, the flagstone meeting place, Points A and B indicate the positions of the objects ' exits, arrows indicate the direction of movement.

It is also useful at this time to suggest reading "ready-made" drawings, for which, for example, it is necessary to give such an assignment: "draw up a drawing issue and write a solution"

5 km 7 km ?

Readers came to such conclusions by analyzing the drawing:

1) the two bodies moved towards each other (arrows indicate that;

2) the first body passed 5 km until it met, and the second body passed 7 km (the flag indicates the meeting place);

3) the matter requires finding an AB path through which the body must pass.

As a result of the analysis of the picture, for example, such an issue is drawn up: “two pedestrians came out from two points towards each other. The first foot walked 5 km until it met, the second 7 km. Find the distance between the points”.

Such preparation can be followed after exercises to solve simple issues related to movement. When solving such issues, we must first focus the students ' attention on the existing connection between the three quantities – distance, speed and time-that relate to the issues related to the action, and, based on this connection, teach the children to correctly choose the actions in which the question of the issue will be solved correctly. But in order for readers to understand the existing connection between these three quantities, they need to clearly understand the meaning of certain terms (words) that are found in issues related to action. Readers should not repeat the words of the matter directly, but understand the essence of each term, understand the life and mathematical story determined by the given term. Take the word” met " for example. The meaning of this word is this: at least two bodies participate in the meeting, the meeting of two bodies always occurs simultaneously, the distance between bodies at the time of meeting is zero (in which the meeting action is considered to be taking place in a straight line).

It is necessary to start solving simple issues of movement by introducing a new amount – speed and clarifying how to understand the sentences (expressions) “the cyclist walked with a speed of 16 km / h”, “walked 4 km / h”. after that, work begins on opening connections between speed, time, distance.

In the methodology of teaching mathematics, issues related to movement include issues related to finding links between the three quantities that characterize movement – speed, time and distance, in which the quantities mentioned participate as directed quantities. In general, the following issues are included in the action:

a) simple and complex issues related to the movement of one body, in these issues one of the quantities – speed, time or distance-participates in depending on the other two;

(B) issues of meeting Action;

v) issues regarding the actions of two bodies in the opposite direction;

g) issues regarding the unidirectional movement of two bodies (this type of issue is not considered in primary school).

It is known that in order for the reader to learn a complex solution, it is necessary to first find out the solution of simple issues. For this reason, it is necessary to start working on issues related to the movement by solving simple issues.
