Development of multimedia technologies and media ethics in modern journalism

Fayzullayeva Khilola Fayzullaevna
Senior teacher of Uzbekistan University of Journalism and Mass Communications

Abstract: The article analyzes the development trends of multimedia elements and their aspects related to media ethics. The process of transition from print media to digital format, the role of multimedia tools in the media space and their impact on the audience were studied. The importance of media ethics principles in the development of multimedia journalism was analyzed, in particular, the problems of information authenticity, the risk of manipulation, personal inviolability, and confidentiality. Multimedia journalism must ensure social trust and the quality of information by strictly adhering to ethical standards.

Keywords: multimedia journalism, media ethics, digital format, visualization, artificial intelligence, information authenticity, manipulation, privacy, ethical standards.

Today, due to technical progress, journalism has developed as a field, has taken its place in social life, and is developing every hour. This can be seen from its technical capabilities, the enrichment of various software, and the mass-communicative nature of the global network. Many large, well-known foreign publications have shifted their activities from print to electronic content. This practice gained momentum in the USA in 2008, in Russia in 2015, and in Europe by 2017. Many well-known Russian publications have found it preferable to conduct their activities in the global network. The reason is that the integration process in the global network provides the opportunity to create a complete information system, combining the functions and features of various media. This means enriching the printed form of the press with full video, audio, and graphic information in electronic format. That is, multimedia elements and properties are envisaged.

That is, one aspect - the infoproduct is the embodiment of several tools. It is the use of sound, image, text to create a single perfect expression. The development of various multimedia elements is associated with technical progress. In fact, humanity has been actively using multimedia elements and graphic drawings since the Stone Age, when it began to write on rock walls. We can see this in various historical archaeological finds dating back to 2-3 thousand years BC. If we look at the history of multimedia, we can see that it was first widely used in countries such as Egypt, India, China, Greece, Rome, which were the centers of ancient evolution and development.

Papyrus papers, clay tablets and similar documents were used to distribute various government announcements, in addition to texts, they were enriched with photos, graphics, and illustrations. While the main goal was to attract public attention, another aspect was to provide understanding to the illiterate people of that time who could not read and write. In addition to imperial decrees in China, the practice of using various images was popular. We can cite this as a vivid example of the first examples of multimedia. It is easy and convenient to absorb and remember information through vision. Humanity has been trying to transform events into visual content for thousands of years. Therefore, the history of visualization dates back to ancient times. However, it is common to think that modern statistical graphs and data visualization appeared later than other areas. In fact, the history of presenting data using visualization methods has deep roots. These roots go back to the prehistoric

VOLUME-5, ISSUE-3

rock carvings of primitive people, to the hieroglyphic inscriptions on the pyramids of ancient Egypt, to the Afrosiab paintings in Samarkand, and to the creation of the oldest maps.

Theoretical ideas about modern multimedia elements were widely studied in the 1960s and 1970s. At that time, multimedia elements were understood as television programs (the exchange of letters in them), various magazines (letters, appeals), and radio broadcasts.

For example, in Japan, a multimedia center was understood as a telecommunications "special combine" that combined all the functions of a television, video recorder, radio, and computer. German scientists, on the other hand, call special gadget drones that provide various visual effects multimedia[1]. Information technology researchers emphasize that multimedia is a special device that provides the ability to perform various services, that is, to enter, store, process and transmit information.

To date, the role of both theoretical and practical fundamental knowledge in the development of multimedia elements is incomparable. The emergence of multimedia tools has caused changes in all areas to varying degrees. In particular, technical support in the last 10 years has made a sharp turn in all views and concepts in the direction of multimedia. The emergence of various large-capacity DVDs, CD-ROMs and similar equivalent memories has provided the opportunity to use visual and text elements more widely in practice.

The development of multimedia tools has a long history, and since ancient times, humanity has sought to visually express information. Today, the widespread use of multimedia technologies has a great impact on the development of digital journalism and the media. The ability to create content in various formats increases the effectiveness of media and helps to convey information to the audience in a convenient and understandable way.

Theoretically, the stages of development of multimedia can be divided into the following processes:

1. The first multimedia programs - the memory capacity of laser video discs in 1984-1990. The practical use of various graphic (non-moving graphic element) interfaces;

2. Large-format memory capacity - the ability to store visual and audio elements in DVD, CD-ROM formats on a single carrier by 1988-1995;

3. The emergence of new generation multimedia programs - the emergence of the Quick Time standard format and MPEG programs, which allow recording digital video images by 1995-2005[2].

The scientist put forward the idea of digitizing all information in alphabetical order in various visual materials. Later, with the creation and popularization of computer programs, this practice began to be widely used in hypertext (the perfect representation of text) and hypermedia (a combination of several media) systems. Today, many media corporations engaged in computer technology and software are pondering about a thousand new interpretations and modern ideas in the field of multimedia practice.

Let's consider some technical issues related to multimedia. Multimedia elements operate with various graphic, visual and audio information. These multimedia features, namely video-image, radio-voice, existed separately 20 years ago. Today, this practice, combined, forms a hypertext as a perfect content.

The basis of multimedia technologies is the technological support that is developing in this information direction. Today, journalism is also expanding and enriching itself with new directions thanks to the development of computer science and digital science. The practical implementation of new technological discoveries has paved the way for a number of directions. In particular, it has turned text into complex hyper-content through images enriched with sound, video, animation and other visual effects. Why is visual content so important? According to statistics, a report by Citrix notes that 63 percent of social media content is visual. That is, almost two-thirds of the news we see in our social network feed is visual content. In addition, almost half of all Internet users have reposted photos or videos downloaded from the Internet. Pew Research provides even more surprising data: 54 percent of network users have published and continue to publish original photos or videos on their social network profiles. Visualization is a form of information presentation that has been used in journalism for centuries, but has become increasingly popular in recent years due to technological advances and the availability of new digital tools. The goal of visualization in journalism is to make complex data easier to understand and engage audiences with more meaningful content. Visualization is often used to show trends, data, or relationships between different elements. This can include the use of maps, charts, graphs, and other visual elements to convey a story or message. Visualization is also widely used to illustrate an event or incident more vividly, such as photos, videos, or animations. The use of visualization in journalism has a long history, with the earliest examples dating back to the 19th century. Early visual elements included maps and diagrams. The availability of new tools and technologies has allowed journalists to create more complex visual elements, such as interactive maps, 3D models, and animations. This has allowed journalists to portray stories in a more interesting and compelling way. In addition, the use of data visualization has become increasingly popular in recent years, with journalists using diagrams, graphs, and other visual elements to illustrate trends in various events. The development of visualization in journalism has also been influenced by the emergence of new platforms such as social media and mobile devices. These platforms have paved the way for journalists to reach a wider audience and create more engaging and interactive visual elements. As a result, visualization has become an important part of modern journalism.[3].

Multimedia is one of the important features of modern journalism, which is closely related to technological progress and the development of information technologies. The use of multimedia elements in journalism has accelerated the transition from print to electronic format. As a result of global network integration, printed materials have been enriched with photo, video, audio and graphic information. This not only makes the information transfer process more efficient, but also allows you to increase the interest of the audience.

Although multimedia has brought journalism to a new level, the importance of adhering to media ethics in this process is increasing. Authenticity, avoiding manipulation, maintaining confidentiality and not violating the context remain important principles for modern journalism.

The development of multimedia elements in journalism directly affects media ethics. As the media increasingly transition to visual and interactive formats, the issues of reliability of information, its absence of manipulation and not misleading the audience are becoming increasingly important. From this point of view, multimedia is closely related to the following principles of media ethics:

Truthfulness and reliability of information. Multimedia content, especially photo and video materials, is prone to manipulation. Incorrect editing of images, taking them out of context, or

VOLUME-5, ISSUE-3

spreading disinformation raises ethical issues. Therefore, journalists are obliged to obtain visual content from reliable sources and verify their authenticity.

Avoidance of manipulation. It has become easier to manipulate the audience's opinion with the help of graphic, audio, and video elements. However, according to the requirements of media ethics, journalists must present neutral information without distorting the truth. For example, excessive use of audio or visual effects to dramatize news can lead to confusion for the audience.

Privacy and privacy. Visual and interactive media materials increase the risk of intrusion into a person's privacy. Images created using drones, hidden cameras, or artificial intelligence can violate human rights. Therefore, journalists must adhere to the principles of human rights and privacy when using multimedia technologies.

Do not mislead the audience and do not distort the context. Visual materials can sometimes change the original content of the news. For example, certain events can be misinterpreted through images or presented as sensational material. Media ethics require refraining from such manipulative methods.

The problem of artificial intelligence and deepfake. In recent years, artificial intelligence (AI) technologies have been widely used in multimedia content. The possibility of creating fake videos and spreading false information using deepfake technologies has increased. Media ethics require journalists to use such technologies with caution and refrain from deceiving the audience.

With the development of multimedia technologies, attention in journalism has increased even more to the veracity and reliability of information. In particular, the possibility of manipulation in visual content is high, which has increased the need to adhere to the principles of media ethics. Journalists should also avoid manipulation, respect the principles of privacy and confidentiality, avoid misleading the audience, and be careful about the problems of artificial intelligence and deepfake.

In modern journalism, the quality of information delivery can be improved through the effective use of multimedia elements. However, in this process, it is necessary to strictly adhere to the principles of media ethics. Providing truthful and reliable information, avoiding manipulation, and not misleading the audience are among the important criteria of today's journalism. Therefore, journalists should use multimedia technologies responsibly and take into account the interests of information consumers.
