Abstract

This study presents a sentiment analysis of news articles manually extracted from the English-language section of the Qalampir.uz website, covering the period from February to March. By applying natural language processing techniques, the study classifies the sentiment of news headlines into three categories: positive, negative, and neutral. The findings indicate that the majority of news content is neutral, with a notable presence of both positive and negative news items. These results provide insights into the tone and focus of recent media coverage in Uzbekistan and contribute to the broader field of computational journalism (Pang & Lee, 2008).

Introduction

News media plays a crucial role in shaping public perception and influencing decision-making (McCombs & Shaw, 1972). Sentiment analysis, a subset of natural language processing (NLP), enables researchers to examine the emotional tone of news content. Previous studies have highlighted the importance of sentiment analysis in journalism, revealing that media bias and sentiment trends significantly impact public opinion (Liu, 2012). This study aims to analyze the sentiment of news headlines published on Qalampir.uz between February and March, providing an overview of how news is framed and disseminated to English-speaking audiences in Uzbekistan.

The rapid advancement of digital journalism has transformed how news is consumed and interpreted. Studies have shown that sentiment in news headlines can affect audience perception and engagement levels (Shoemaker & Vos, 2009). Given the increasing reliance on digital news platforms, it is essential to analyze how sentiment trends develop over time and influence public discourse. By employing computational techniques, this study contributes to a growing body of research exploring the intersection of technology and journalism.

Literature Review

Sentiment analysis has been widely used in media and journalism research. Pang and Lee (2008) describe sentiment analysis as a critical tool for understanding textual data in digital media. Several studies have demonstrated that news sentiment can influence financial markets (Tetlock, 2007), social behavior (Bollen et al., 2011), and political discourse (González-Bailón et al., 2013). The growth of digital journalism has increased the need for sentiment analysis tools that can process vast amounts of textual data efficiently (Liu, 2012). While previous research has focused on major global news outlets, studies specifically analyzing sentiment in Uzbekistani media remain limited.

Theoretical frameworks such as agenda-setting theory (McCombs & Shaw, 1972) and framing theory (Entman, 2007) provide insight into how media influences public perception through selective reporting. Sentiment analysis bridges these theories with computational methods, allowing researchers to quantify media sentiment trends systematically. Additionally, recent advancements in

artificial intelligence have improved sentiment classification accuracy, with models such as BERT and LSTM outperforming traditional lexicon-based approaches (Devlin et al., 2019).

Methodology

To conduct the sentiment analysis, news headlines were manually collected from the English-language section of Qalampir.uz. The dataset underwent preprocessing, including text normalization, tokenization, and removal of special characters (Manning et al., 2008). The sentiment of each headline was determined using TextBlob, an NLP tool that classifies text based on polarity scores:

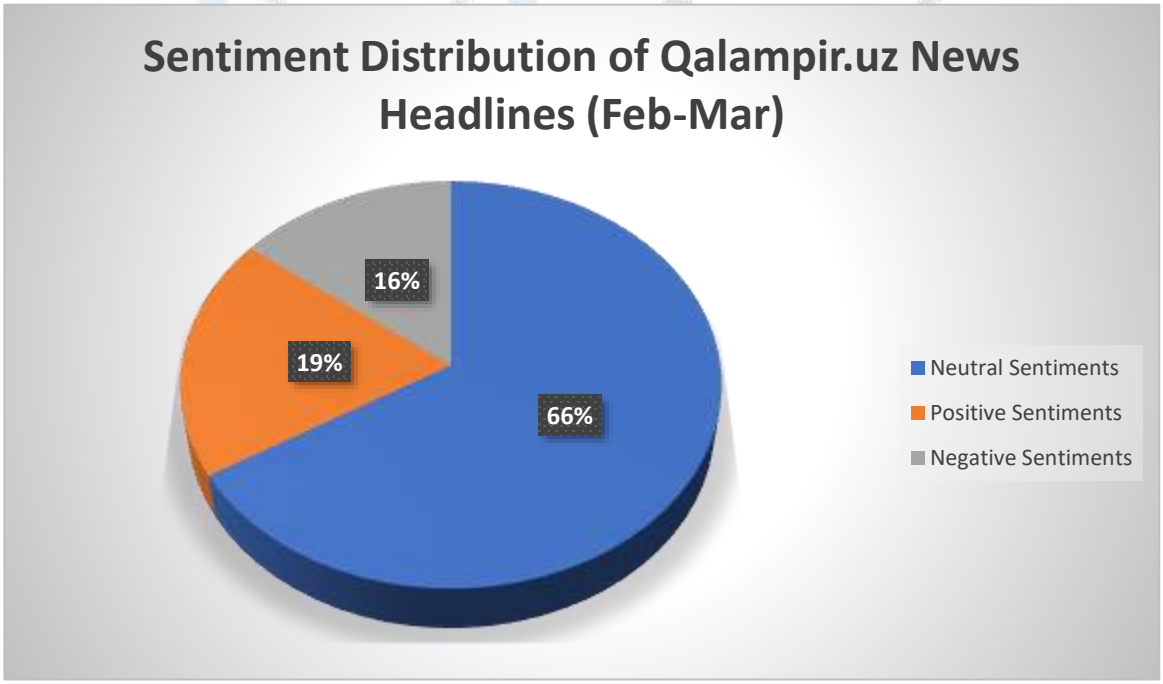

- **Positive sentiment:** If the polarity score is greater than 0.
- **Negative sentiment:** If the polarity score is less than 0.
- **Neutral sentiment:** If the polarity score is equal to 0.

A total of 914 headlines were analyzed. The results were statistically examined to understand the distribution of sentiment in the dataset. Descriptive statistics and frequency analysis were used to interpret the data trends (Field, 2013). Data visualization techniques, such as bar charts and pie charts, were employed to illustrate the sentiment breakdown, providing a clearer representation of trends in the dataset.

Results and Discussion

The analysis of 914 news headlines revealed the following sentiment distribution:

- **Neutral Sentiments:** 606 headlines (66.3%)
- **Positive Sentiments:** 176 headlines (19.2%)
- **Negative Sentiments:** 132 headlines (14.5%)

The dominance of neutral sentiment suggests that the majority of news articles from Qalampir.uz adopt an objective or factual reporting style (Tuchman, 1978). The presence of positive news indicates a focus on achievements, developments, and uplifting events, while negative news reflects incidents such as accidents, fraud, and political tensions.

A qualitative review of the headlines shows that negative sentiment is often associated with crime reports, warnings, and political conflicts (Entman, 2007). In contrast, positive sentiment headlines

2024-6.875 ResearchBib IF: 9.948 / 2024

highlight economic growth, diplomatic successes, and social advancements. The findings align with global media trends, where neutral reporting predominates, yet a balance of positive and negative stories exists to capture public interest (Shoemaker & Vos, 2009).

Further examination of the dataset highlights variations in sentiment across different news categories. Political news exhibited a higher degree of negative sentiment compared to economic or cultural news. Reports on social issues tended to have a more neutral tone, reflecting an attempt to present facts rather than opinions. The results suggest that news sentiment may be influenced by the editorial policies of Qalampir.uz, as well as broader sociopolitical conditions in Uzbekistan.

Additionally, comparing these findings with global media sentiment trends suggests that Uzbekistani news maintains a relatively balanced approach, with a higher prevalence of neutral reporting. This could be attributed to media regulations, cultural factors, or editorial guidelines that prioritize factual reporting over emotional framing. Future studies could explore sentiment trends across multiple media sources to determine whether this pattern is consistent across different news platforms.

Limitations and Future Research

While this study provides an insightful overview of sentiment trends in Uzbekistani news media, it has certain limitations. First, the analysis was limited to headlines, which may not fully reflect the sentiment of entire articles (Reis et al., 2015). Additionally, using TextBlob, which relies on lexical sentiment analysis, may not capture nuanced sentiment patterns (Liu, 2012). Future research could incorporate advanced machine learning models, such as BERT or LSTM, for improved sentiment classification (Devlin et al., 2019).

Expanding the dataset to include articles from other Uzbekistani news sources would provide a more comprehensive view of media sentiment trends. Further research could explore cross-linguistic sentiment analysis to compare sentiment variations between English and Uzbek-language news. Additionally, employing sentiment trend analysis over longer timeframes would allow for the detection of shifts in media tone based on evolving political and social events.

Conclusion

This sentiment analysis of Qalampir.uz's English-language news provides a valuable perspective on the tone of media reporting in Uzbekistan. The study underscores the role of computational techniques in media analysis and paves the way for further research into sentiment trends over extended periods. By understanding the emotional framing of news, policymakers, journalists, and researchers can better assess media influence on public perception and discourse (McCombs & Shaw, 1972). Incorporating sentiment analysis into journalism studies enhances our ability to critically evaluate media content and its societal implications.
