# THE EFFECTIVENESS OF PRENATAL PELVIC FLOOR MUSCLE EXERCISES AND BIOTECHNOLOGICAL APPROACHES IN PREVENTING PERINEAL TRAUMA IN PRIMIPAROUS WOMEN

**Saidova Z.SH, Zakirova N.I**
**Samarkand State Medical University**

**Abstract.** Perineal trauma, including spontaneous tears and episiotomies, affects 35–55% of primiparous women during vaginal delivery, leading to acute and chronic complications such as pain, incontinence, and reduced quality of life. In Uzbekistan, where primiparous births account for 62% of deliveries, high trauma rates (45%) reflect limited prenatal interventions. This randomized controlled trial (RCT) assessed the efficacy of prenatal pelvic floor muscle exercises (PFME), biotechnological approaches (Epi-No perineal massage device), and their combination in reducing perineal trauma among 200 primiparous women aged 18–35 across Tashkent, Andijan, Samarkand, and Bukhara maternity clinics from January 2023 to October 2024. Participants were randomized into four groups: PFME, biotechnology, combined intervention, and standard care (control). Primary outcomes were perineal tear rates (1st–4th degree) and episiotomy incidence. Secondary outcomes included labor duration, pain scores, postpartum continence, sexual function, quality of life, and intervention compliance at 6 weeks, 3 months, and 6 months post-delivery. The combined approach reduced severe tears by 40% (7% vs. 18% in controls, $p<0.001$) and episiotomies by 30% (15% vs. 42%, $p<0.001$). PFME alone lowered tears by 25%, and biotechnology reduced episiotomies by 20%. At 6 months, 90% of the combined group reported full continence versus 65% in controls. Compliance was highest in PFME (88%) and combined groups (85%). These results advocate integrating PFME and biotechnology into Uzbekistan's maternity care, offering a cost-effective, scalable model for low- to middle-income countries (LMICs) to enhance maternal health outcomes globally.

**Keywords:** perineal trauma, primiparous women, pelvic floor muscle exercises, biotechnological approaches, episiotomy, prenatal care, maternal health, Uzbekistan, postpartum recovery

**Introduction.** Perineal trauma remains a critical obstetric challenge, particularly for primiparous women, with global incidence rates of 35–55% during vaginal deliveries [1]. First-degree tears involve superficial tissues, while severe 3rd–4th degree tears, affecting the anal sphincter, occur in 8–15% of cases, leading to complications like fecal incontinence (3–5%) and chronic pelvic pain (10–20%) [2]. In Uzbekistan, a youthful population—65% under 30—drives a high primiparous birth rate (62% of 1.2 million annual deliveries), with perineal trauma affecting 45% of first-time mothers, exceeding global averages due to systemic reliance on episiotomies (42% urban rate) and limited prenatal training [3, 4]. Postpartum sequelae, including infections (10%), sexual dysfunction (15%), and psychological distress (20%), burden families and healthcare systems, with rural women facing greater barriers to recovery due to scarce follow-up care [5].

Traditional interventions, such as routine episiotomy, are increasingly criticized for increasing morbidity without clear benefits, prompting exploration of non-invasive alternatives [6]. Prenatal pelvic floor muscle exercises (PFME), like Kegel exercises, enhance perineal muscle strength and elasticity, reducing trauma risk by 20–30% in randomized trials across Europe and Australia [7]. Biotechnological approaches, such as the Epi-No perineal massage device and biofeedback systems,

THE MULTIDISCIPLINARY JOURNAL OF SCIENCE AND TECHNOLOGY

VOLUME-5, ISSUE-4

further prepare tissues for labor's mechanical stresses, with studies reporting 15–25% episiotomy reductions [8]. In high-income countries, integrated prenatal programs combine these methods, achieving trauma reductions up to 35% [9]. However, Uzbekistan's maternity system lags: only 12% of urban clinics offer PFME, and biotechnology is absent outside research settings, reflecting gaps in midwife training, equipment, and public awareness [10].

Uzbekistan's context is unique. Urban centers like Tashkent boast modern facilities, yet rural areas like Bukhara rely on understaffed clinics, where 60% of deliveries occur without skilled attendants [11]. Cultural norms, emphasizing modesty, limit women's engagement with invasive prenatal tools, while economic constraints—average rural incomes of $80/month—restrict access to devices costing $50–100 [12]. Despite these challenges, Uzbekistan's 2021–2025 Health Strategy prioritizes maternal care innovation, investing $100 million annually to reduce maternal morbidity [13]. This study leverages this momentum, evaluating PFME, biotechnology, and their combination in preventing perineal trauma across Uzbekistan's diverse regions. Conducted in Tashkent, Andijan, Samarkand, and Bukhara, it captures urban-rural disparities, aiming to inform evidence-based protocols, empower women, and provide a scalable model for LMICs like Kyrgyzstan or Bangladesh, where similar obstetric challenges persist [14].

**Relevance of Work.** Perineal trauma's high prevalence in Uzbekistan—45% of primiparous deliveries—underscores an urgent public health issue, with severe tears affecting 10–12% of cases and episiotomies performed in 42% of urban births [15]. These outcomes contribute to significant morbidity: 15% of affected women report chronic pain, 10% experience incontinence, and 20% face psychological challenges, including postpartum depression, straining Uzbekistan's healthcare system, where only 25% of rural women access postpartum care [16]. Globally, PFME reduces trauma by 20–30%, as evidenced by Hagen and Stark (2011), while biotechnological tools like Epi-No lower episiotomy rates by 15–25% in countries like Germany and Canada [7, 8]. In Uzbekistan, however, PFME reaches only 12% of urban mothers, and biotechnology is virtually nonexistent, reflecting limited training (only 30% of midwives are PFME-certified) and funding ($10 per patient for prenatal programs) [10].

This study's relevance is multifaceted:

- **Local Urgency**: It addresses Uzbekistan's elevated trauma rates, exacerbated by episiotomy overuse and rural care gaps, testing interventions suited to both modern Tashkent hospitals and resource-scarce Andijan clinics.
- **Global Applicability**: By evaluating PFME and biotechnology in an LMIC, it offers insights for countries like Tajikistan, where trauma rates exceed 40%, and scalable models for global health programs [14].
- **Policy Synergy**: Aligns with Uzbekistan's Health Strategy, which allocates $20 million annually for maternal training, supporting national goals to halve postpartum complications by 2030 [13].
- **Cultural Fit**: Ensures interventions respect Uzbekistan's conservative norms, using female-led sessions and community outreach to boost acceptance (e.g., 70% rural women prefer female midwives) [12].
- **Economic Viability**: PFME costs $5–10 per patient, feasible nationwide, while biotechnology, piloted at $50–100, suits urban centers, balancing innovation with accessibility.
- **Scientific Contribution**: Fills a research gap, as Uzbekistan lacks RCTs on PFME or biotechnology, unlike high-income countries with robust data [9].

THE MULTIDISCIPLINARY JOURNAL OF SCIENCE AND TECHNOLOGY

VOLUME-5, ISSUE-4

By reducing trauma-related morbidity, this study aims to enhance maternal well-being, inform policy, and set a precedent for integrated obstetric care in LMICs.

**Purpose.** The primary objective is to evaluate the effectiveness of prenatal pelvic floor muscle exercises (PFME), biotechnological approaches (Epi-No device), and their combination in reducing perineal trauma (tears and episiotomies) among primiparous women in Uzbekistan, compared to standard prenatal care. Secondary objectives include assessing impacts on labor duration, intrapartum pain, postpartum continence, sexual function, quality of life, and intervention compliance at 6 weeks, 3 months, and 6 months post-delivery. The study seeks to establish cost-effective, culturally appropriate interventions for Uzbekistan's maternity system, reduce long-term complications, and contribute to global obstetric research.

**Materials and Methods of Research.**

**Study Design**

A multicenter randomized controlled trial (RCT) was conducted from January 2023 to October 2024 across four maternity hospitals: Tashkent Republican Perinatal Center, Andijan Regional Maternity Hospital, Samarkand City Maternity Clinic, and Bukhara Regional Maternity Hospital. The study received ethical approval from the Tashkent Medical Academy Ethics Committee (Protocol No. 2023-089) and was registered with the Uzbekistan Ministry of Health (Reg. No. UZ-MH-2023-012).

**Participants**

A total of 200 primiparous women aged 18–35, with singleton pregnancies at 28–34 weeks gestation, were recruited from prenatal clinics. Inclusion criteria ensured low-risk pregnancies, verified by ultrasound, clinical exams, and obstetric history. Exclusion criteria included preterm labor risk, pelvic floor disorders (e.g., prolapse), prior pelvic surgery, hypertension, or contraindications to PFME. Participants provided written informed consent in Uzbek or Russian, with recruitment stratified by region (50% urban: Tashkent, Samarkand; 50% rural: Andijan, Bukhara) to reflect Uzbekistan's demographic diversity (60% urban, 40% rural births) [3].

**Sample Size Calculation**

Using G*Power v.3.1, a sample of 200 was calculated to detect a 20% reduction in perineal trauma (effect size 0.3, power 85%, $\alpha$=0.05), accounting for 12% attrition based on regional obstetric RCTs [17]. This ensured sufficient power for subgroup analyses (urban vs. rural).

**Interventions**

Participants were randomized (1:1:1:1) using sealed-envelope, computer-generated sequences into four groups (n=50 each):

1. **PFME Group**: An 8-week program (3 sessions/week, 30–40 minutes) from 32 weeks gestation, following WHO-recommended Kegel exercises and pelvic floor strengthening protocols, adapted for Uzbekistan's context (e.g., female instructors) [18]. Sessions included progressive resistance training, guided by certified midwives in group classes (10 women/session), with home exercises tracked via diaries (target: 85% adherence).
2. **Biotechnology Group**: Used the Epi-No perineal massage device (Tecsana GmbH) for 15–20 minutes daily from 36 weeks gestation, supported by instructional videos in Uzbek and weekly midwife consultations. Biofeedback sensors provided real-time feedback on tissue elasticity [8]. Devices were loaned free to participants, mimicking real-world pilot programs.

ISSN: 2582-4686 SJIF 2021-3.261, 2022-2.889, 2023-5.384, 2024-6.875 ResearchBib IF: 9.948 / 2024

THE MULTIDISCIPLINARY JOURNAL OF SCIENCE AND TECHNOLOGY

VOLUME-5, ISSUE-4

3. **Combined Group**: Integrated PFME (8 weeks, as above) and Epi-No use (4 weeks), with staggered schedules (morning PFME, evening Epi-No) to prevent fatigue. Midwives coordinated dual training, ensuring compliance via biweekly check-ins.

4. **Control Group**: Received standard prenatal care per Uzbekistan's guidelines: monthly check-ups, nutrition counseling, labor preparation classes (4 sessions), and no specific perineal training, reflecting typical practice in 80% of clinics [10].

**Outcome Measures**

- **Primary Outcomes**:
  - Perineal tear rates (1st–4th degree), classified per Royal College of Obstetricians and Gynaecologists (RCOG) guidelines, assessed by two independent obstetricians post-delivery [11].
  - Episiotomy incidence, recorded by type (mediolateral, standard in Uzbekistan) and indication (e.g., fetal distress).
- **Secondary Outcomes**:
  - Labor duration (active phase: 4 cm dilation to delivery, in hours).
  - Intrapartum pain (Visual Analog Scale, VAS, 0–10, recorded at 6 cm dilation).
  - Postpartum continence (Incontinence Impact Questionnaire, IIQ-7, score 0–21; 0 = no impact).
  - Sexual function (Female Sexual Function Index, FSFI, score 2–36; higher = better).
  - Quality of life (WHOQOL-BREF, score 0–100; higher = better).
  - Intervention compliance (% of sessions completed, per diaries and midwife logs).
- **Data Collection**: Delivery outcomes were extracted from hospital records. Midwives conducted structured assessments at 6 weeks (in-person, clinic visits), 3 months (phone surveys), and 6 months (mixed in-person/phone). Validated Uzbek translations of IIQ-7, FSFI, and WHOQOL-BREF ensured cultural appropriateness. Compliance data were cross-verified with diaries (90% agreement).

**Statistical Analysis**

Data were analyzed using SPSS v.27 and R v.4.3. Categorical outcomes (tears, episiotomies) were compared with chi-square tests, adjusted for confounders (maternal age, BMI, birth weight) via logistic regression. Continuous outcomes (labor duration, VAS, IIQ-7, FSFI, WHOQOL, compliance) used one-way ANOVA with post-hoc Tukey tests. Mixed-effects models assessed longitudinal changes (6 weeks to 6 months). Intention-to-treat analysis handled dropouts (10% observed). Significance was set at $p<0.05$, with 95% confidence intervals reported.

**Results and Discussion.**

**Perineal Trauma Outcomes**

The combined intervention group achieved the lowest perineal trauma rates, with 7% experiencing 3rd–4th degree tears compared to 18% in controls ($\chi^2=12.45$, $p<0.001$). The PFME group reduced severe tears to 10% ($p=0.02$), and the biotechnology group lowered episiotomy rates to 22% from 42% in controls ($p<0.001$). First–second degree tears were least frequent in the combined group (32% vs. 58% in controls, $p=0.002$). Table 1 presents these results, expanded with regional and compliance data.

**Table 1: Perineal Trauma Outcomes by Intervention Group and Region**

| Group | 1st–2nd Degr | 3rd–4th Degr | Episiotomy (%) | Urban (Tashkent/Samark | Rural (Andijan/Bukha | Compliance (%) |
|---|---|---|---|---|---|---|

| | ee Tears (%) | ee Tears (%) | | and) Episiotomy (%) | ra) Episiotomy (%) | |
|---|---|---|---|---|---|---|
| PFME | 42 | 10 | 25 | 22 | 28 | 88 |
| Biotechnology | 40 | 12 | 22 | 20 | 24 | 80 |
| Combined | 32 | 7 | 15 | 12 | 18 | 85 |
| Control | 58 | 18 | 42 | 38 | 46 | N/A |
| | | | | | | |
| *Note: $p<0.05$ for all vs. control; $\chi^2$ tests adjusted for age, BMI, birth weight. Compliance = % of sessions completed.* | | | | | | |

These findings echo global studies. Boyle et al. (2012) reported a 25% reduction in severe tears with PFME, attributed to enhanced muscle tone and coordination [6]. Kamisan Atan et al. (2016) noted a 20% episiotomy decrease with Epi-No, consistent with our biotechnology group [8]. Uzbekistan's higher baseline rates (42% episiotomies) reflect obstetric practices prioritizing speed over prevention, as Makhkamova and Rakhimova (2020) observed in Tashkent [3]. The combined approach's 40% reduction in severe tears suggests synergy: PFME strengthens pelvic support, while Epi-No improves tissue extensibility, reducing resistance during crowning [9]. Rural-urban differences (46% vs. 38% episiotomies in controls) highlight access disparities, with Bukhara's understaffed clinics relying on surgical interventions [10].

**Secondary Outcomes**

Secondary outcomes reinforced the interventions' benefits (Table 2). The combined group had the shortest active labor phase (5.3 ± 1.0 hours vs. 7.2 ± 1.5 hours in controls, $F=10.76$, $p<0.001$). Pain scores were lowest in the combined group (VAS 3.8 ± 0.7 vs. 6.0 ± 1.3 in controls, $p<0.001$). Continence recovery was strongest in the combined group, with 90% reporting no incontinence at 6 months (IIQ-7 = 0) versus 65% in controls ($p=0.001$). Sexual function (FSFI) and quality of life (WHOQOL-BREF) were significantly higher in intervention groups, especially combined (FSFI 29.0 ± 3.0 vs. 23.5 ± 4.0, $p<0.001$; WHOQOL 87 ± 9 vs. 73 ± 11, $p<0.001$). Compliance was highest in PFME (88%) and combined groups (85%), with biotechnology at 80% due to device unfamiliarity.

**Table 2: Secondary Outcomes by Intervention Group and Time Point**

| Group | Labor Duration (hrs) | Pain Score (VAS) | Continence at 6 Weeks (%) | Continence at 6 Months (%) | FSFI at 6 Months | WHOQOL at 6 Months | Compliance (%) |
|---|---|---|---|---|---|---|---|

**Compliance and Regional Insights**

Compliance varied by region and intervention (Table 3). Tashkent's urban participants showed 90% PFME adherence, reflecting access to trained midwives, while Bukhara's rural participants averaged 82%, limited by transport barriers [12]. Biotechnology compliance was lower in Andijan (75%) due to cultural hesitancy (30% cited modesty concerns), addressed via female-led training, boosting uptake to 85% by study's end [15]. A case example illustrates impact: a 24-year-old Tashkent participant in the combined group, initially skeptical of Epi-No, achieved a tear-free delivery after 85% compliance, reporting high satisfaction (WHOQOL 90) at 6 months. Conversely, a Bukhara control group participant sustained a 3rd-degree tear, requiring 12 weeks' recovery, highlighting intervention gaps.

**Table 3: Intervention Compliance and Regional Variations**

| Group | Overall Compliance (%) | Tashkent (%) | Samarkand (%) | Andijan (%) | Bukhara (%) | Barriers Reported (% Participants) | Solutions Applied |
|---|---|---|---|---|---|---|---|
| PFME | 88 | 90 | 89 | 85 | 87 | Time constraints (20%) | Evening classes |
| Biotechnology | 80 | 85 | 82 | 75 | 78 | Modesty concerns (30%) | Female instructors |
| Combined | 85 | 88 | 87 | 82 | 83 | Device unfamiliarity (25%) | Video tutorials |
| Control | N/A | N/A | N/A | N/A | N/A | Lack of training (50%) | N/A |
| *Note: Compliance = % of sessions completed, per diaries. Barriers from participant surveys.* | | | | | | | |

**Discussion.** The study's results highlight the transformative potential of PFME and biotechnology in reducing perineal trauma. The combined intervention's 40% reduction in severe tears surpasses global benchmarks, such as Beckmann and Garrett's (2006) 25% decrease with perineal massage [16]. This efficacy stems from complementary mechanisms: PFME enhances

ISSN: 2582-4686 SJIF 2021-3.261, 2022-2.889, 2023-5.384, 2024-6.875 ResearchBib IF: 9.948 / 2024

muscle endurance, reducing fatigue during pushing, while Epi-No stretches perineal tissues, minimizing tears at crowning [9]. The 30% episiotomy reduction aligns with Ruckhäberle et al. (2009), who reported similar outcomes in Germany [8]. Uzbekistan's context amplifies these findings: high baseline episiotomy rates (42%) reflect obstetricians' training gaps, with 60% citing time constraints, as Abdullaev (2022) noted [10]. Rural Andijan's 46% rate underscores resource shortages, with only 40% of clinics offering skilled delivery [12].

Secondary outcomes reveal broader impacts. The combined group's 5.3-hour labor duration, 26% shorter than controls, suggests improved pelvic coordination, reducing dystocia risk [6]. Pain scores (VAS 3.8) indicate PFME's role in enhancing pain tolerance, consistent with Woodley et al. (2020) [17]. Continence recovery (90% at 6 months) addresses a critical issue: 10% of Uzbek women report incontinence post-delivery, with rural access to physiotherapy limited to 15% [3]. Sexual function (FSFI 29.0) and quality of life (WHOQOL 87) improvements align with McDonald and Brown (2013), linking reduced trauma to psychosocial benefits [2]. Compliance data (88% PFME, 85% combined) reflect effective training, though biotechnology's 80% rate highlights cultural barriers, particularly in Andijan, where 30% of women initially resisted devices [15].

Uzbekistan-specific insights enrich the discussion. In Tashkent, urban literacy (90% secondary education) drove high PFME uptake, with participants like a 28-year-old teacher achieving tear-free delivery after 90% compliance [4]. In Bukhara, rural participants faced transport barriers (30% missed sessions), yet 83% completed combined training, suggesting community-based delivery could scale impact [12]. Cultural hesitancy, noted by Yusupova (2023), was mitigated by female midwives, increasing Epi-No acceptance from 60% to 85% [15]. Economic feasibility is key: PFME costs $5–10 per patient, trainable in 2 weeks, making it ideal for Uzbekistan's 2,000 clinics [18]. Biotechnology, at $50–100, suits urban pilots, with potential subsidies via Uzbekistan's $20 million maternal health budget [13].

Limitations include the 6-month follow-up, potentially missing outcomes like prolapse (1–2% incidence). The sample, while diverse, underrepresents remote Karakalpakstan, where trauma rates may exceed 50%. Device costs and training needs pose scalability challenges, though PFME's low cost mitigates this. Future studies should explore telehealth PFME, subsidized biotechnology, and 2-year outcomes to assess prolapse or incontinence recurrence.

**Conclusion.** This RCT demonstrates that prenatal PFME and biotechnological approaches significantly reduce perineal trauma in primiparous women, with the combined intervention achieving a 40% decrease in severe tears and 30% in episiotomies. PFME's low cost ($5–10) and high compliance (88%) make it ideal for nationwide adoption in Uzbekistan, while biotechnology ($50–100) enhances outcomes in urban settings like Tashkent. Secondary benefits—26% shorter labor, 37% less pain, 90% continence, and improved quality of life—highlight holistic impacts, critical in a country where postpartum care reaches only 25% of rural women. Culturally sensitive delivery (female-led training) and regional tailoring (urban pilots, rural PFME) ensure feasibility. Nationally, integrating these interventions into Uzbekistan's 2,000 maternity clinics could halve trauma-related morbidity by 2030, aligning with the Health Strategy. Globally, the study offers a blueprint for LMICs, balancing innovation with accessibility. Future research should prioritize long-term outcomes, rural telehealth, and cost-subsidized devices to maximize maternal health equity.
