**Abstract.** In today's world, it is rare for a person not to have encountered a coronavirus infection. The symptoms that all individuals who have had it experience are well-known, including fever, cough, nasal discharge, difficulty breathing, and loss of smell. The impact of the coronavirus infection is not only related to its severe progression and risk of death, but also to its negative effects on human health. Patients who have undergone COVID-19 often face many negative consequences, and among the most prominent are mental, emotional, cognitive, and vegetative issues that significantly affect quality of life, slow down the rehabilitation process, and make it more difficult to return to previous activities. This article is dedicated to analyzing the diseases and syndromes related to changes in mental state commonly observed in patients who have recovered from COVID-19, with a focus on studying their causes. The material from global research into the progression of the disease and its negative effects on human life was used during the work.

**Keywords:** COVID-19, mental disorders, fatigue, cognitive disorders, asthenovegetative syndrome, memory impairment.

**Relevance of the Topic:** The COVID-19 virus can have a significant impact on not only physical health but also mental health. The infection can affect not only the physical condition but also the psycho-emotional state of individuals. The main reason for this is the virus's interaction with both social and psychological factors among people, as well as its direct psychological effects. The post-COVID syndrome is becoming a significant issue, impacting both health and quality of life. Numerous scientific studies are being conducted on the long-term consequences observed in patients who have contracted COVID-19, particularly its effects on physical and mental health. Since the epidemic began, the World Health Organization (WHO) has been conducting research not only on the symptoms and course of the disease but also on its future consequences. The main method of obtaining objective data about the long-term consequences of the disease is the mass surveys conducted among patients who have recovered from COVID-19. Results of surveys and research conducted in various countries reveal that the patients surveyed belong to various age groups, nationalities, professions, living standards, and mental health statuses. These studies focus on identifying the physical and mental impacts of post-COVID syndrome, providing valuable information about its effects on the patients' lifestyle, work capacity, and social activity. Scientists explain the cognitive consequences of COVID-19 through either the pathogen's direct effect or the body's immune mechanisms. This version is supported by the findings of studies on patients who recovered successfully from the disease. Asthenia, as a manifestation of post-COVID syndrome, is widespread among those who have had COVID-19 or its complications. This condition negatively

affects both the physical and mental state of patients, making it difficult for them to perform daily activities. According to research conducted by scientists from different countries, symptoms of asthenic syndrome can vary among patients who have recovered from COVID-19. Survey results show that between 18.5% and 65% of patients report experiencing symptoms of asthenic syndrome. In patients treated in intensive care and resuscitation departments, this figure rises to 73%. After two to three months, 54% of patients still exhibit post-COVID asthenia, and 17.5% of patients may experience chronic fatigue symptoms after six months. Problems and cognitive deficiencies may persist for over six months, indicating the long-term effects of the virus. These studies help form a clearer understanding of the post-COVID consequences and demonstrate that comprehensive rehabilitation approaches are needed for the full recovery of patients.

**Conclusion.** COVID-19 and other pathologies rarely proceed without mental disorders. This is why, today, special attention is being paid to the comprehensive rehabilitation of patients, which not only targets their physical recovery but also aims to improve the mental state of those affected by COVID-19. Rehabilitation courses should be offered to all individuals who have contracted the virus. Furthermore, the close relatives of the patients should also undergo these courses, especially for patients with symptoms such as memory and attention difficulties, chronic fatigue, heightened anxiety, and post-traumatic stress disorders. Currently, there is no definitive data on which rehabilitation methods are most effective and in what situations, but many doctors are utilizing cognitive-motor rehabilitation. These rehabilitation methods include memory and attention exercises, work with speech therapists, and activities to enhance cognitive abilities. Psychological support is crucial during rehabilitation, aimed at normalizing the mental state and addressing stress, anxiety, and depression. Such rehabilitation can be conducted in group or individual sessions, in person or remotely, with each patient choosing the format that works best for them. Psychological assistance can be provided at any stage of the disease, and it is not necessary to wait for complete recovery before starting the sessions. Assistance may also be extended to family members, which in turn reduces anxiety and stress for other family members, including parents, children, spouses, and friends.
