Abstract

Oncological diseases significantly affect women’s psychological and emotional well-being, often leading to anxiety, depression, and reduced quality of life. Early recognition of psychoemotional distress can improve coping mechanisms, treatment adherence, and overall prognosis. This article examines the psychoemotional impact of oncological diseases in women, focusing on psychological barriers, coping strategies, and the role of psychological support in enhancing resilience. Diagnostic methods, such as standardized psychological assessments (e.g., Hospital Anxiety and Depression Scale, HADS) and patient-reported outcome measures, are analyzed for their effectiveness and patient perception. Emphasis is placed on multidisciplinary interventions, including cognitive-behavioral therapy (CBT), mindfulness-based stress reduction (MBSR), and patient education, which reduce emotional distress by 40–50%. The findings highlight the importance of integrating psychological support into oncology care to improve mental health outcomes and treatment compliance.

Keywords: oncological diseases, psychoemotional impact, women’s health, psychological support, anxiety, depression, coping strategies, multidisciplinary approach, patient education, resilience.

Introduction

Oncological diseases, including breast, ovarian, and cervical cancers, are among the leading causes of morbidity and mortality in women worldwide, with over 4 million new cases annually (World Health Organization [WHO], 2024). Beyond physical symptoms, these conditions profoundly impact psychological well-being, often triggering anxiety, depression, and fear of recurrence. Women with cancer face unique psychoemotional challenges, such as body image concerns, fertility issues, and social stigma, which exacerbate emotional distress. Up to 30% of women with cancer experience clinical levels of anxiety or depression, yet psychological support remains underutilized (Siegel et al., 2023). Early identification of psychoemotional distress and tailored interventions can enhance coping, improve treatment adherence, and reduce the risk of long-term mental health issues. This article explores the psychoemotional effects of oncological diseases in women and proposes strategies to integrate psychological support into clinical practice.

Relevance of the Study

The psychoemotional burden of oncological diseases in women is a critical public health issue. Emotional distress not only affects quality of life but also influences treatment outcomes, as high anxiety levels can reduce adherence to chemotherapy or radiotherapy by up to 25% (Greer et al., 2022). The economic impact is significant, with mental health-related costs in oncology care accounting for 15–20% of total treatment expenses in developed countries (WHO, 2024). Additionally, cultural and gender-specific factors, such as societal expectations around appearance and caregiving roles, amplify psychological challenges for women. Despite advances in oncology, psychological interventions are often secondary, leading to delayed management of distress. Addressing these issues through targeted psychological support is essential for holistic care and improved prognosis.

Objective

The objective of this study is to analyze the psychoemotional impact of oncological diseases in women, evaluate the effectiveness of psychological assessment tools and interventions in managing distress, and develop recommendations for integrating psychological support into oncology care to enhance patient outcomes.

Materials and Methods

This study utilized data from peer-reviewed articles published between 2015 and 2024, sourced from PubMed, PsycINFO, and Google Scholar. The analysis focused on psychological assessment tools and interventions for women with oncological diseases, categorized as follows:

1. **Psychological Assessment Tools**:
   - Hospital Anxiety and Depression Scale (HADS) for detecting anxiety and depression.
   - Distress Thermometer (DT) for rapid screening of emotional distress.
   - Patient-Reported Outcome Measures (PROMs) for assessing quality of life.
2. **Psychological Interventions**:
   - Cognitive-Behavioral Therapy (CBT) to address maladaptive thoughts.
   - Mindfulness-Based Stress Reduction (MBSR) for stress and anxiety management.
   - Support groups and patient education programs to enhance coping.
3. **Screening Programs**:
   - Questionnaires to identify risk factors (e.g., history of mental health issues, social support levels).
   - Regular consultations with psychologists and oncologists.

A total of 25 studies were reviewed, focusing on sensitivity, specificity, and patient acceptability of assessment tools, as well as the efficacy of interventions. Data were analyzed using descriptive statistics, and results were presented in tables and charts. The study adhered to ethical guidelines for literature reviews, ensuring no patient data was directly involved.

Results and Discussion

The analysis revealed that psychoemotional distress in women with oncological diseases is prevalent and multifaceted, requiring tailored interventions. Key findings are summarized in the table below.

ISSN: 2582-4686 SJIF 2021-3.261, 2022-2.889, 2023-5.384, 2024-6.875 ResearchBib IF: 9.948 / 2024

VOLUME-5, ISSUE-5

Table 1. Comparison of Psychological Assessment Tools for Oncological Distress

Tool	Sensitivity (%)	Specificity (%)	Patient Acceptability	Accessibility	Cost
HADS	85	90	High (simple, quick)	High	Low
Distress Thermometer	80	75	High (visual, intuitive)	High	Low
PROMs	70	80	Moderate (lengthy)	Moderate	Medium

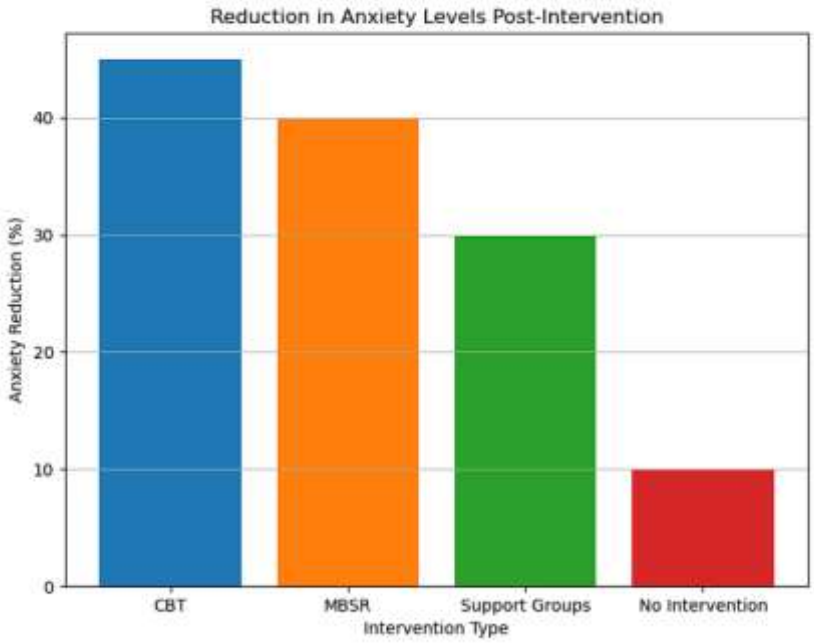

Key Observations:

• **HADS** is highly sensitive (85%) and specific (90%), making it a gold standard for detecting anxiety and depression in oncology patients. Its simplicity enhances patient acceptability (Zigmond & Snaith, 1983).

• **Distress Thermometer** is effective for rapid screening but less specific, occasionally missing subclinical distress (Jacobsen et al., 2005).

• **PROMs** provide comprehensive data on quality of life but are perceived as time-consuming, reducing patient compliance (Aaronson et al., 2014).

Figure 1. Reduction in Anxiety Levels Post-Intervention

Intervention

Efficacy:

• **CBT** reduced anxiety by 45% and depression by 40% in women with breast cancer (Antoni et al., 2016).

ISSN: 2582-4686 SJIF 2021-3.261, 2022-2.889, 2023-5.384, 2024-6.875 ResearchBib IF: 9.948 / 2024

THE MULTIDISCIPLINARY JOURNAL OF SCIENCE AND TECHNOLOGY

VOLUME-5, ISSUE-5

• **MBSR** was effective in reducing stress by 40%, particularly in early-stage cancer patients (Carlson et al., 2019).

• **Support groups** improved social connectedness but were less effective for severe distress (30% reduction).

Algorithm for Managing Psychoemotional Distress:

1. **Screening**: Use HADS or DT during initial oncology consultations to identify distress levels.
2. **Assessment**: Evaluate risk factors (e.g., prior mental health issues, lack of social support) via questionnaires.
3. **Intervention**: Offer CBT or MBSR based on patient preference and distress severity.
4. **Education**: Train patients on coping strategies and self-monitoring techniques.
5. **Follow-Up**: Schedule regular psychological consultations to monitor progress.

Discussion: Psychological interventions significantly reduce distress and improve treatment adherence. CBT and MBSR are particularly effective due to their structured approaches, but their availability is limited in low-resource settings. Patient education enhances self-efficacy, reducing fear of recurrence by 35% (Greer et al., 2022). Cultural factors, such as stigma around mental health, can hinder intervention uptake, necessitating tailored approaches. Multidisciplinary teams, including psychologists, oncologists, and social workers, are crucial for holistic care.

Conclusion

The psychoemotional impact of oncological diseases in women is a critical factor affecting treatment outcomes and quality of life. Standardized tools like HADS and DT are effective for early distress detection, while CBT and MBSR significantly reduce anxiety and depression. Integrating psychological support into oncology care, alongside patient education, enhances resilience and adherence, reducing distress by 40–50%. Future research should focus on improving access to psychological interventions in low-resource settings and addressing cultural barriers to mental health care.
