THE EFFECT OF PROPER NUTRITION ON IMMUNITY IN CHILDREN

Yusupov Sh.R., Ibraximova H.R., Sadullaev S.E.

Urgench branch Tashkent medical academy, Urgench, Uzbekistan.

Abstract This article discusses the importance of proper nutrition in the healthy growth and development of infants, as well as the composition and characteristics of breast milk. It also highlights the role of oligosaccharides in breast milk in the formation of the child's immune system.

Keywords: breast milk, children, nutrition, nutrients, gastrointestinal system, hormones.

One of the key factors in a child's healthy growth and development is adequate and quality nutrition. Proper nutrition in both quantity and quality is the foundation for hormonal growth and development, adaptation to environmental changes, and strong immunological resistance. It is important to note that children under the age of one are very sensitive to disruptions in nutrition. This is because, during the first year of life, the body undergoes rapid cell formation. If sufficient cells are not formed during this critical time, they cannot be compensated for later. This is especially true for the central nervous system, which is particularly sensitive. For instance, two-thirds of brain cells are formed at birth, with the remaining developing in the first few months. Inadequate nutrition during this period can lead to developmental delays. Therefore, ensuring proper nutrition in early childhood is of vital preventive importance.

Breast milk is the most physiologically, morphologically, and biochemically suitable food for the infant's body. Feeding a baby with breast milk is known as natural feeding. Breast milk is a crucial nutritional factor for a child. The composition and proportion of breast milk components are specifically tailored to meet the demands of the growing infant. During the early months, when the baby's body cannot produce sufficient immune cells, natural feeding ensures hormonal development and protects the child from infectious diseases. Statistically, exclusively breastfed infants are 2.5 times less likely to get sick compared to those who are formula-fed, and 25 times less likely to suffer from gastrointestinal diseases.

Additionally, constant physical contact between mother and baby promotes warmth and emotional bonding, easing the adaptation of the mother to postpartum life and the child to the social environment. In the first 3–4 days after birth, the baby receives colostrum, and from the 6–7th day onward, mature milk. Colostrum is a thick, yellowish liquid richer in protein, especially in albumin and globulin, than mature milk, and it closely resembles the protein content of newborn blood plasma. The fat in breast milk is structurally aligned with the infant's fat tissue. It contains 34–37% saturated fatty acids (especially palmitic acid at 17–25%), 31–43% oleic and palmitoleic acids, and 12–26% unsaturated fatty acids. These proportions vary depending on the lactation stage and maternal diet. Lipids are a vital energy source and building material for cell membranes, and they are essential for hormone production and the absorption of vitamins and trace elements.

Docosahexaenoic acid (DHA) and alpha-linolenic acid are omega fatty acids necessary for the healthy functioning of the brain and eyes. DHA plays a key role in cognitive function, memory, and emotional regulation. It stimulates metabolism and helps prevent cardiovascular diseases. A deficiency in these vital nutrients can lead to skin and nervous system issues, vision problems, sleep disorders, and allergic diseases.

Breast milk carbohydrates mainly consist of lactose and oligosaccharides. Lactose accounts for 6.8% of the carbohydrates and oligosaccharides for about 1%. Lactose aids in calcium absorption and

breaks down into glucose and galactose, which are vital for brain development. There are more than 130 types of oligosaccharides in breast milk. These serve as bifidus factors, meaning they promote the growth of beneficial gut bacteria. They are not digested and do not serve direct nutritional functions, but oligosaccharides are considered the third-largest component in breast milk after lactose and fat. Mature breast milk contains 10–15 g/L of oligosaccharides.

Oligosaccharides are categorized chemically into three groups:

- Neutral fucosylated (e.g., 2'-fucosyllactose or 2FL),
- Neutral non-fucosylated (e.g., LNnT),
- Acidic sialylated (e.g., 3-SL).

Neutral oligosaccharides make up about 75% of total oligosaccharides, with 2FL being the most abundant (over 30%). Research shows that 70–80% of immune-supporting cells reside in the infant's intestines, and oligosaccharides begin their functions upon entering the gut. These compounds are the first natural prebiotics, providing nourishment only for beneficial microflora. They act as decoys for pathogenic bacteria, preventing their attachment to cells.

Oligosaccharides boost cellular resistance against infectious agents, strengthen communication between immune cells, and contribute to the development of a healthy immune system.

Proteins in breast milk are mainly made up of amino acids, each playing a vital role in the child's growth and development. Breast milk contains 0.9–1.0% protein, which is 2–3 times less than cow's milk. In the first days of lactation, the whey-to-casein protein ratio is 90:10, shifting to 60:40 in mature milk.

Breast milk contains a broad range of immune factors, especially immunoglobulin A (IgA), which primarily protects mucous membranes — the main entry point for pathogens. Secretory IgA resists digestive enzymes and forms a protective layer on mucosal surfaces. Infants receive about 0.5 g of secretory IgA per day through breast milk. Enzymes like lysozyme and lactoferrin also play key roles; lactoferrin makes up 10–15% of breast milk and helps prevent infections.

Breast milk contains over 600 types of beneficial bacteria, most notably bifidobacteria. Oligosaccharides assist in the formation of intestinal microflora and provide direct resistance against pathogens. Compared to other mammals, the amount of oligosaccharides in human breast milk is 10 to 100 times greater.

Conclusion In addition to requiring a full spectrum of nutrients for proper growth and development, an infant needs protection against many infections and support in the formation of a robust immune system from birth. Breastfeeding — and, when not possible, the correct selection of adaptive formula milk — is the key to healthy infant growth and immune development.
