SCIENTIFIC-THEORETICAL FOUNDATIONS OF MIGRATION PROCESSES AND THEIR STUDY

Gulhayot Shuhratovna Abdullayeva
Senior Lecturer, Tashkent Oriental University and Independent Researcher, Tashkent State University of Economics
agulhayot@gmail.com

Abstract: This article examines the essence and conceptual meaning of migration, the main types of migration categorized by various purposes and factors, and the scientific-theoretical foundations of its study. It examines the works of international and Uzbek scholars who have conducted research in the field of migration. The historical development, stages of evolution, current issues of migration processes, and their possible solutions are analyzed.
Keywords: International migration, external migration, internal migration, migrant, trend, immigrant, emigrant.

Introduction. Population migration represents the movement of individuals (migrants) across regional or national boundaries, either permanently or temporarily, for varying durations. The term migration is derived from the Latin word migratio, which translates as “relocation” or “movement”. The phenomenon of people changing their place of residence for diverse purposes including land acquisition, income generation, education, and political motives whether permanently or temporarily, is commonly referred to as the mechanical movement of the population.

Human migration constitutes an interdisciplinary field within the study of social processes, producing wide-ranging consequences for both individuals and society at large. Hence, migration is often conceptualized as a demographic, economic, ethnological, geographical, political, psychological, or sociological process. As a result, the range of academic disciplines engaged in the study of migration is continuously expanding. This includes, but is not limited to, demography, economics, geography, political science, and sociology. Each of these disciplines approaches migration from a distinct analytical lens. For instance, demographers regard migration as one of the key determinants of population dynamics and structural changes. Economists, in contrast, focus on the economic dimensions of migration, particularly its implications for national, regional, and individual welfare[1].

Types of Migration According to Key Characteristics.

I. By Geographical Scope

1. International (External) Migration.
2. Internal Migration.
3. Transit Migration.

International migration. Also referred to as cross-border migration, international migration encompasses the movement of individuals from their country of origin to other regions or nations. This category includes the concepts of immigration and emigration.

VOLUME-5, ISSUE-6

Immigration – refers to the inflow of individuals into a country for the purposes of employment, education, or long-term residence. It is frequently associated with changes in citizenship and family reunification.

Emigration – denotes the departure of individuals from their country of origin to reside temporarily or permanently abroad, either voluntarily or involuntarily.

International migration can be further subdivided into intercontinental (e.g., from Europe to the United States or Australia) and intracontinental movements (e.g., within European countries).

Internal Migration. This involves the movement of people within the borders of a single country, for example, from one region or city to another. In the context of Uzbekistan, such migration includes flows from rural to urban areas, urban to rural areas, and between cities and villages.

Transit Migration. Transit migration refers to temporary movement through one or more intermediary countries en route to a final destination. A notable example includes migrants and refugees who leave their countries of origin, travel through parts of Europe or North Africa by air, and continue onward by land or sea in an attempt to cross into the European Union, often through irregular means.

II. By Duration.

Permanent Migration. This refers to the long-term or indefinite relocation of individuals from one place to another, such as from rural to urban areas or across national borders. This type of migration may occur within a country or between countries.

Temporary Migration. Temporary migration can be seasonal or pendulum-like (cyclical). Seasonal migration typically occurs in connection with agricultural activities.

Pendulum migration involves frequent movements between residential areas and urban centers for purposes such as employment, education, or daily commuting. Conversely, urban residents may travel to surrounding rural areas for leisure, religious visits, or subsistence farming.

III. By Purpose.

Labor Migration. Labor migration includes internal and external movements in pursuit of employment. It reflects individuals' spatial mobility driven by job opportunities, income levels, or labor market dynamics.

Educational Migration. This encompasses international and domestic student mobility for academic purposes. It includes schoolchildren, college and university students, postgraduates, doctoral candidates, interns, and professionals seeking advanced training in educational or organizational institutions.

Recreational Migration. Also referred to as leisure migration, this involves movements aimed at satisfying social needs such as rest, tourism, cultural enrichment, or household and domestic interests.

IV. By Organizational Structure.

Organized Migration. Organized migration refers to state-regulated, legal, and secure pathways for migration, particularly for employment abroad. It is often part of governmental policies designed to reduce illegal migration and ensure the protection of migrants.

Independent Migration. Independent migration is primarily associated with unaccompanied minors (under the age of 18) who choose to relocate and reside in a different country without the guardianship of parents or legal custodians.

V. By degree of compulsion.

VOLUME-5, ISSUE-6

Voluntary Migration. Voluntary migration arises from a combination of "push" and "pull" factors. These may include economic or political instability, poverty, lack of access to education or health services, and the desire for better living standards, safer environments, or higher-quality education.

Forced Migration. This includes the displacement of individuals due to armed conflicts, environmental and technological disasters (e.g., nuclear accidents or famine), and large-scale development projects. The term also encompasses refugees and internally displaced persons.

Review of literature on migration.

The earliest scientific studies on migration were conducted by the English geographer and statistician Ernst Georg Ravenstein, who is regarded as the founding father of migration theory. In 1885, Ravenstein published his seminal work "The Laws of Migration" in the Journal of the Statistical Society[2]. Based on an analysis of migration patterns in the United Kingdom and other countries, Ravenstein formulated the following eleven foundational principles:

1. **Most migration occurs over short distances.** Ravenstein found that approximately 75% of migration takes place to the nearest destination that offers adequate opportunities. This reflects the human tendency to minimize effort in achieving desirable outcomes. Although international migration garners significant attention, internal migration often involves a much larger number of people.
2. **Migration occurs in stages.** The concept of stepwise migration suggests that migrants tend to relocate incrementally, often working in intermediate locations before reaching their final destination. Although subject to debate, this process is still observed under certain conditions.
3. **Long-distance migration typically targets major economic and industrial centers.** About 25% of migrants relocate over long distances, often directly to metropolitan hubs such as London or New York, where they tend to settle rather than continue onward. This trend has led major port cities to become focal points of international migration.
4. **Each migration stream generates a counter-stream.** For every inflow of migrants, there is a corresponding outflow from the same region. Ravenstein's concept of "counter-currents" remains relevant in analyzing contemporary migration dynamics.
5. **Urban residents are generally less mobile than rural populations**. This assertion has been largely challenged by subsequent research, which has shown that urban dwellers may be equally or even more mobile under specific conditions.
6. **Within national borders, women migrate more frequently; internationally, men predominate**. This was particularly true in 19th-century Britain, where women migrated domestically for domestic service, while men were more likely to migrate abroad.
7. **Migrants are predominantly adults; families are less likely to migrate internationally.** During the 19th century, most migrants were individuals aged 20 and older. Even today, international migration flows are often dominated by young adults aged 15 to 35, especially along major migration corridors such as the U.S.–Mexico border.
8. **Urban population growth is largely driven by migration rather than natural increase.** Urbanization is accelerated more by inward migration than by high birth rates, a trend still observable in rapidly growing urban centers globally.
9. **The scale of migration increases with the development of industry, commerce, and transportation**. Though Ravenstein could not empirically verify this claim, later research has

demonstrated that improved transportation infrastructure and economic opportunity strongly influence migration intensity.

10. **Migration is predominantly rural-to-urban.** This continues to be a dominant pattern globally. Reverse migration—urban to rural—is rare and usually driven by extraordinary circumstances such as conflict, natural disasters, or government resettlement programs.

11. **Economic motives are the primary drivers of migration.** According to Ravenstein, individuals migrate primarily for better employment opportunities and higher income. This principle remains central in both internal and international migration today.

Of the eleven laws proposed, nine remain widely applicable in current academic discourse, and they continue to provide a foundational framework for migration studies. Ravenstein's emphasis on economic motivation has had a lasting influence on migration modeling and theory development[3].

Another prominent contributor to migration theory is Everett S. Lee, an American sociologist. In his 1966 article "A Theory of Migration", Lee revisited Ravenstein's push-pull framework, emphasizing that both origin and destination points are associated with positive and negative factors. These include social desires (e.g., living near family) and obstacles (e.g., language barriers, legal restrictions)[4].

Lee highlighted the influence of intervening obstacles—factors such as distance, transportation costs, differences in income and living expenses, housing availability, and legal restrictions. These factors vary in significance for different individuals, sometimes acting as insurmountable barriers. His model accounts for the broad range of economic, political, cultural, and environmental forces influencing migration. According to Lee, migration decisions are shaped by the individual's subjective evaluation of these forces.

A key figure in development economics, Sir W. Arthur Lewis, also made substantial contributions through his dual-sector model, which explains labor migration from rural to urban areas in developing countries. His theory inspired further research by economists such as Fei, Ranis, Harris, Todaro, Doringer, Piore, and Stiglitz.

Of particular note are the works of John R. Harris and Michael P. Todaro, who authored the influential article "Migration, Unemployment and Development: A Two-Sector Analysis" (1970), published in the American Economic Review. Harris, an expert on African economies, based much of his research on labor markets in Nigeria and Kenya[5].

Sociologist Saskia Sassen, a prominent scholar in globalization, urban studies, and international migration, introduced the concept of the "global city." In her book "The Mobility of Labor and Capital," she argued that foreign direct investment in developing countries often increases emigration rather than reducing it. The influence of globalization on migration is further explored in the work of Stephen Castles and Mark Miller, "The Age of Migration"[6].

Sassen asserts that migration is a multifaceted phenomenon and should not be driven by short-term political trends. She emphasizes the role of international organizations in shaping migration flows (see "Regulating Immigration in a Global Age: A New Policy Landscape")[7].

In Uzbekistan, one of the most recognized researchers in the field of population migration is economist Qalandar Khodjayevich Abdurakhmanov. His research spans demography, labor resource distribution, and labor migration. His contributions include the textbook "Demography" and monographs such as "Uzbekistan: Strategic Directions and Development Prospects" and "New Trends in Economics and Education," which address unemployment, migration, and economic development.

Methodology. This study employs a combination of qualitative and quantitative research methods to explore the mechanisms and implications of migration processes. The research is grounded in the analysis of academic literature, statistical data, and comparative economic indicators. Key methodological tools include: Logical reasoning and conceptual abstraction, grouping and classification of migration-related data, comparative analysis of demographic and economic variables, synthesis and interpretation of trends and patterns. hese methods are applied to understand both historical and contemporary migration dynamics and to assess their socio-economic impact at national and regional levels.

Findings and Analysis. Migration has a long and complex historical trajectory. During the 18th and 19th centuries, the evolution of demographic trends coincided with the expansion of international trade networks, the establishment of maritime ports, and the emergence of industrial regions. European countries were the primary drivers of emigration during this period.

For instance, the United Kingdom ranked first in terms of the number of emigrants, with approximately 13 million people migrating between 1815 and 1900, primarily to the United States (65%), Canada (15%), Australia (9%), and South America (5%)[8]. Germany held the second position, with over 4.85 million emigrants leaving the country between 1841 and 1900.

Italy's migration patterns were distinct, characterized by seasonal and pendulum-like migration flows. Italian laborers, including builders and land developers, typically traveled to Austria, the Balkan states, Switzerland, and France in early spring and returned home in late autumn[9].

In the contemporary era, migration has become a complex global phenomenon, commanding increasing attention from governments and international organizations. The majority of international migrants today are labor migrants, whose economic contributions significantly affect both sending and receiving countries.

Labor migration supports various sectors requiring intensive labor, including agriculture, construction, and personal services. It also contributes to:

- rejuvenating the labor force;
- stimulating entrepreneurship;
- raising household living standards;
- addressing labor shortages in critical industries.

Remittances sent by migrants to their families play a vital role in the economic development of their countries of origin, serving as a supplementary source of national income[10].

In recent decades, urban areas in many parts of the world have continued to grow primarily due to immigration rather than natural population increase. For example, Austin, Texas, has an annual population growth rate exceeding 3%, of which only 0.4% is attributed to natural increase, while the remaining 2.6% is driven by net immigration. This supports Ravenstein's proposition that urban growth is significantly shaped by migratory inflows.

In contrast, cities such as Philadelphia, with an annual growth rate of 0.48%, derive only 0.08% of that growth from natural increase. Similarly, despite China's national natural growth rate of just 0.3%, many of its fastest-growing urban centers report annual growth rates of up to 5%, primarily driven by internal migration[11].

Conclusion and Recommendations.

Human mobility is a fundamental mechanism that contributes to both societal development and individual well-being. Migration—understood as the movement of individuals from one region to another due to environmental, economic, or social factors—has historically been one of the essential conditions for the advancement of social life. It is widely recognized as a core driver in the formation of modern migration patterns.

In certain contexts, unresolved social challenges have acted as underlying factors in the intensification of migration processes, particularly when individuals are compelled to seek improved living standards or escape conflict, poverty, or exclusion. Migration is a continuous and evolving global process and remains a central topic of political and socio-economic debate. Worldwide, people migrate both voluntarily (for economic, educational, or social reasons) and involuntarily (due to war, ethnic conflict, or natural disasters). Managing migration flows has become a critical concern for both developed and developing nations.

The diversity of motivations and directions behind migration generates additional challenges for national governments, as migratory movements have far-reaching implications for the economy, demographic structure, and cultural landscape of both sending and receiving countries. Therefore, it is essential that governments, particularly in developing countries, conduct in-depth analyses of the determinants of migration and study the best practices of developed nations in migration governance. In this regard, crafting evidence-based migration policies, supported by interdisciplinary research and international cooperation, is vital to ensuring that migration contributes to inclusive development, regional stability, and human capital formation.
