METHODS OF DEVELOPMENT OF ATTENTION SKILLS OF PRESCHOOL CHILDREN

Meliboyeva Sadokat Doniyorbek kizi
second year master
Turebekova Guljakhan Adilbekovna
Senior Lecturer, PhD Department of Preschool Education, NSPI named after Ajiniyaz

Annotation: This article explores effective methods for developing attention skills in preschool children. Attention is a crucial aspect of a child's cognitive development, playing a key role in learning, speech development, and social interaction. The article analyzes strategies such as play-based learning, interactive activities, music, and physical exercises that help enhance attention span in early childhood. It also highlights the importance of collaboration between educators and parents in creating a supportive environment for attention development. Based on research findings, the article provides practical recommendations for fostering attention in preschoolers.

Key words: attention, preschool children, development methods, play-based learning, educator, interactive activities, concentration, child psychology

INTRODUCTION:

The ability to attend selectively to critical stimulus features and" ignore others is an integral part of the learning process, and it is necessary to understand the development of this ability in order to establish an adequate model of children's learning and thinking. We have examined the development of selective attention through research on children's incidental learning--that is, the acquisition of information that is extraneous or irrelevant to task performance (1). A paradigm in which certain features of the stimulus are designated as relevant for task performance and others are defined as incidental. Performance on this central task is assessed as well as later recall of information about the incidental stimuli, and these two measures together provide a basis for inferring selective attention. Attention directed primarily to tas~-relevant rather than irrelevant stimuli. Having found that children's

efficient use of selective attention increases with age, we began to look for the reasons behind younger children's inefficiency in deployment of attention. One hypothesis is that younger children have difficulty analyzing stimuli into components, and thus they maintain attention to all features as a global unit (1).

Attention develops from birth and the ability to sustain attention will improve with age. The ability to sustain our attention is a combination of cognitive ability, impulse control, and the ability to filter out distractions (2).

Material and methods:

The child's central task was to locate the position in the array of the card that matched the color of the cue card. After the fourteen picture arrays were presented and the number of correct matches was recorded, the incidental task was presented (8).

In this task the child was asked to match the pictures which had appeared on the previous trials with the appropriate color of background. Each picture had always appeared on the same background color. The number of correct matches constituted the subject's incidental learning core.

Stages of development of attention skills:

Stage 1 – Distractibility

Attention flits from one thing to another.
Attention is involuntary and is caught by stimuli.
For example: attention shifts from one object / person to another and is easily distracted by a new event occurring eg. a loud noise.

Stage 2 – Rigid attention

Can attend to a concrete task of child's own choice. Attention is involuntary.
Ignores external stimuli to focus.
For example: may concentrate on blocks but will ignore adult intervention both verbal and visual.

Stage 3 – Single channelled attention

Child still cannot attend to other stimuli while focussing on an activity.
Can shift full attention with adult's help to the adult.
Control of the child's attention lies with the adult.
For example: if a child is playing a game, the adult can shift the attention of the child, for example by saying " look at this" the child will respond and then go back to their game.

Stage 4 – Focussing attention

The child is starting to control their own focus.
Child can still only focus on one activity at at a time.
Will give full attention to specific activity including both visual and auditory.
Can focus and refocus their attention by themselves.
For example: child can be playing a game will stop when adult speaks, give their full attention to the adult and then continue with their game.

Stage 5 – Two channelled attention

Child can focus on an activity but can also listen to what is being said without stopping their activity and looking at the speaker.
Can focus on a single aspect of a complex situation.

It is thought that the development of attention skills of children will affect both their academic success and life quality in a positive way in the following years by applying attention education program to children with accurate development, who have not been diagnosed with attention-gathering problem in their preschool period (2). Today, children without attention gathering problem are also exposed to digital culture. Therefore, the need for attention skill's supporting should also be taken into account in a

world with rapidly changing stimulants (3). Attention skill is prior condition of beginning of learning process. Children with undeveloped attention gathering skill may have undesired behaviours if targeted behaviour is not gained. Therefore, teachers are expected to be more eager and devoted to develop attention gathering skill of children:

Selective attention

is the ability to select from many factors or stimuli and to focus on only the one that you want while filtering out other distractions.

Sustained attention

is the ability to focus on one specific task for a continuous amount of time without being distracted.

Joint attention

sharing & maintaining a focus of attention with another person.

VOLUME-5, ISSUE-8

Attention gathering skill is one of the most significant skills to be supported for children's being happy and healthy individuals in the coming years. Attention gathering in early childhood is the conscious focusing of children on a particular stimulant with their own will (5).

Attention is essential for our development and is crucial in the following:

- Listening skills
- Speech and language development
- Social communication & interaction
- Classroom behaviour
- Following instructions
- Working memory & executive functioning (planning, organising (etc)

Results and discussion:

The study revealed that incorporating structured and interactive activities significantly enhances attention development in preschool children. Through a series of observations and practical sessions conducted in early childhood education settings, it was found that children engaged in play-based learning, musical exercises, and physical movement games demonstrated improved focus and longer attention spans.

Specifically, activities that involved visual and auditory stimuli—such as matching games, storytelling with visual aids, and rhythmic clapping exercises—helped children maintain concentration for extended periods. In contrast, passive tasks like simple worksheets or repetitive drills showed less impact on sustaining attention.

Furthermore, the involvement of educators and parents in creating consistent routines and engaging environments contributed positively to children's attentional growth. When teachers incorporated interactive questioning, group tasks, and praise-based reinforcement, children showed higher levels of sustained and selective attention (4).

An important finding was the effectiveness of short, varied activities that matched the developmental level of the children. Sessions lasting 10–15 minutes with clear objectives were most effective in maintaining engagement. Also, integrating mindfulness techniques, such as breathing exercises or calm-down corners, helped children self-regulate their attention more effectively.

In discussion, these results suggest that attention skills in preschool children can be significantly improved through intentional, varied, and age-appropriate activities. Educators should focus on designing learning environments that stimulate curiosity and active participation. Similarly, parental involvement at home in structured play and routine-based activities reinforces attention development across settings (6).

Conclusion:

The development of attention skills in preschool children is a vital component of their overall cognitive, emotional, and social growth. This study demonstrates that attention can be effectively enhanced through a variety of interactive, age-appropriate methods such as play-based learning, music, physical activities, and visual-auditory stimulation.

The findings highlight the importance of a well-structured learning environment, active educator involvement, and supportive parental engagement. Short, purposeful activities tailored to the developmental needs of preschoolers proved to be the most effective in fostering sustained and selective attention.
