В статье рассматривается процесс разработки программного интерфейса, предназначенного для проектирования технологических процессов в швейной промышленности. Представлены основные этапы создания — от анализа пользовательских требований и изучения существующих производственных процессов до проектирования архитектуры, программной реализации и тестирования. Обоснована значимость каждого этапа, что обеспечивает создание функционального, удобного и интуитивно понятного программного решения, направленного на повышение эффективности труда и улучшение качества готовой продукции в швейном производстве.

This article explores the development process of a software interface designed for planning technological processes in clothing manufacturing. It outlines the main stages of development — from studying user requirements and analyzing current workflows to designing the interface architecture, software development, and testing. The paper highlights the importance of each stage, contributing to the creation of efficient, user-friendly, and intuitive software that enhances productivity and improves the quality of finished garments in the apparel industry.

Ключевые слова: программный интерфейс, системы автоматизации, проектирование технологических процессов, цифровая трансформация, интерактивное моделирование, производство швейных изделий.

Keywords: interface, software, technological processes, automation, digitalization, interactive models, clothing production.

Introduction. Modern technologies are rapidly integrating into all spheres of production, including the garment industry. The automation and digitalization of technological processes greatly improve efficiency, product quality, and production speed. One of the most important directions in this field is the development of specialized software that supports the design of technological processes at various stages of garment manufacturing.

Literature Review. Today's manufacturing enterprises represent complex systems that perform numerous technological operations on a daily basis. To ensure the coordinated functioning of each production unit and the effective execution of tasks, various specialized software solutions have been created to automate production workflows. The introduction of such software for process automation has become one of the main tools driving progress across different industrial sectors [1,2].

This study examines existing software systems used for production management:

Research Methodology. The main objective of this study is to explore in detail the stages involved in developing a software interface for designing technological processes, to justify the significance of each stage, and to analyze the resulting outcomes.

1. Requirements Analysis and Task Definition

1.1 Studying User Needs.

The first stage focuses on identifying the requirements of end users — such as designers, technologists, and sewing machine operators. Surveys and interviews are conducted to determine their primary tasks, challenges, and expectations from the software.

1.2 Workflow Analysis.

A comprehensive analysis of existing production workflows is carried out to identify inefficiencies and determine which processes should be automated. The analysis covers all stages — from product design and development to final quality control.

2. Interface Architecture Design

2.1 Conceptual Model Development.

Based on collected data, a conceptual interface model is created. The design emphasizes logical structure and ease of user interaction. Key modules, their interconnections, and functional requirements for each component are defined at this stage.

2.2 Prototype Creation.

Interface prototypes are developed — starting with simple sketches and evolving into interactive models. These prototypes help visualize the expected layout and functionality, allowing users to evaluate and suggest improvements before full-scale software implementation.

3. Interface Implementation

VOLUME-5, ISSUE-11

3.1 Technology Selection.

Appropriate tools, programming languages, frameworks, and libraries are chosen to ensure a user-friendly and intuitive interface. Special consideration is given to cross-platform compatibility, system performance, and scalability.

3.2 Interface Development.

The programming phase involves translating the prototypes and architecture into a functional interface. The focus is placed on usability, ergonomics, and design aesthetics. Integration with databases and internal systems ensures seamless software operation.

4. Testing and Optimization

4.1 Internal Testing.

The initial testing is conducted by the development team to detect and fix errors, optimize performance, and verify that all modules meet the defined requirements and functions.

4.2 User Testing.

The next phase includes beta testing with actual end users. Feedback collected during this process helps identify usability issues, enhance functionality, and improve the interface design. Necessary adjustments are made based on user recommendations.

5. Deployment and Maintenance

5.1 Implementation.

Following successful testing, the software interface is deployed into the production environment. This includes installation, configuration, and staff training to ensure effective use of the new system.

5.2 Technical Support and Updates.

Regular maintenance and software updates are essential to maintain performance and adapt to evolving production requirements. The development team continues to enhance functionality, fix bugs, and ensure compatibility with new technologies and workflows [3,4,5].

Analysis and results. The developed software facilitates the automation of routine operations, simplifies the planning and control process, and enables quick response to changes in the production process. Implementing such a tool allows garment manufacturing companies to remain competitive in the face of constantly growing market demands and technological innovations.

Conclusion/Recommendations. Developing software interface for designing technological processes in garment manufacturing is indeed a complex, multi-stage process that requires careful attention to each phase. From thorough requirements gathering and analysis of current workflows to meticulous testing and software deployment, every stage plays a crucial role in creating an effective and user-friendly tool. Successfully implementing such a project can significantly increase productivity, reduce costs, and improve the quality of the final product.

Analysis and Results. The developed software system has demonstrated a significant positive impact on the organization and efficiency of technological processes within garment manufacturing enterprises. By automating repetitive and time-consuming operations, the software reduces human error and frees up employees to focus on higher-level analytical and creative tasks. The system streamlines planning, coordination, and monitoring activities across departments, ensuring that production schedules are maintained and resources are optimally allocated. One of the most valuable outcomes of this development is the improved responsiveness of production management to real-time changes. The interface provides immediate access to operational data, enabling managers and

VOLUME-5, ISSUE-11

technologists to make informed decisions quickly. This flexibility is especially important in modern garment production, where frequent model updates, fluctuating material supplies, and changing customer demands require rapid adaptation.

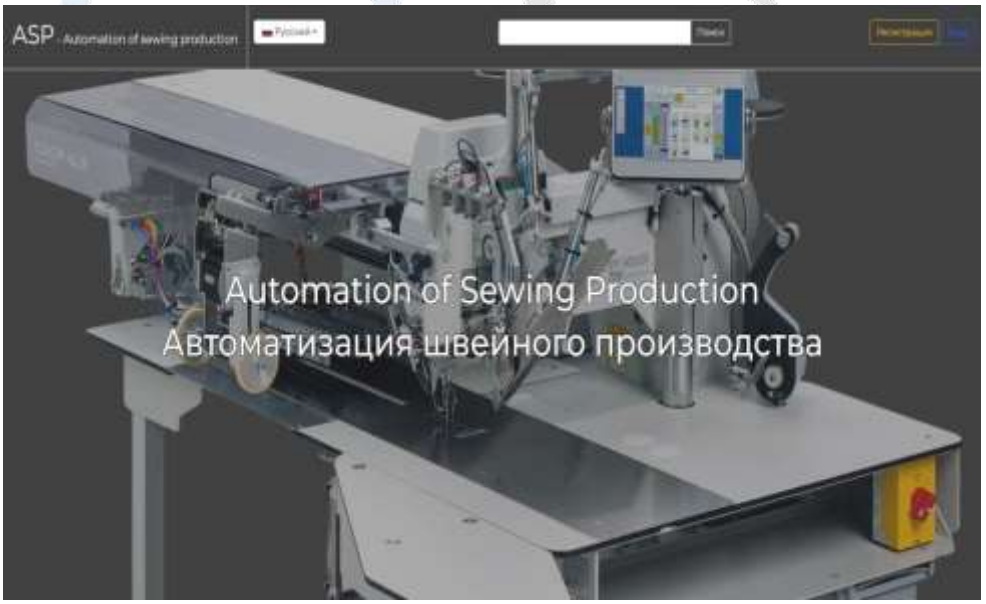

In addition, the integration of this interface with other digital systems—such as computer-aided design (CAD), enterprise resource planning (ERP), and quality control modules—creates a unified information environment. This contributes to better communication between departments, transparency of production stages, and traceability of technological operations. As a result, production downtime is reduced, the efficiency of material usage increases, and the overall productivity of the enterprise improves [6,7,8].

Moreover, the software enhances the quality management process by enabling detailed analysis of production parameters and the identification of deviations at early stages. Automated data collection and processing allow for more accurate forecasting, continuous process optimization, and maintenance of consistent product quality standards. Implementing such a digital tool allows garment enterprises to strengthen their competitiveness and ensure sustainable development in a rapidly evolving market driven by technological innovation.

In the course of this research, a software interface for managing the operations of garment manufacturing enterprises was developed. The main panel of the system includes essential functions such as “Language Selection,” “Search,” “User Registration,” and “System Login.” The interface of the “ASP – Automation of Sewing Production” MES software system was developed for designing automated technological processes in garment manufacturing enterprises (Figure 2.)

Figure 2. Main panel of the “ASP – Automation of Sewing Production” MES software system.

From a scientific and engineering standpoint, the design of these interface components ensures user accessibility, data security, and system adaptability to different operating conditions. The inclusion of

multilingual support enhances the software’s usability across various regions, while the integrated search and authentication mechanisms facilitate efficient navigation, personalized access, and data integrity.

Furthermore, the modular architecture of the developed interface allows for scalability and integration with other digital subsystems such as production planning, quality control, and inventory

management. As a result, the system not only improves the efficiency of administrative and technological operations but also contributes to the digital transformation and intelligent management of garment manufacturing enterprises.

Conclusion and Recommendations. The development of a software interface for designing technological processes in garment manufacturing represents a complex and multi-faceted engineering and research task. It requires a systematic approach that integrates knowledge from software engineering, production technology, ergonomics, and design thinking. Each stage of the development cycle—from initial requirements analysis and modeling of workflows to software architecture design, interface prototyping, testing, and implementation—plays a vital role in achieving a functional and efficient solution. A thorough understanding of end-user needs is the cornerstone of success. The interface must be intuitive, logical, and tailored to the real conditions of sewing production, where operators, technologists, and designers interact with different types of information and tasks. Equally important is ensuring the system's flexibility and scalability, allowing it to adapt to future technological upgrades and expansions in production capacity.

Comprehensive testing and iterative refinement of the software are essential to achieve stability, performance, and ease of use. Continuous feedback from actual users during the beta testing stage helps to refine the interface and eliminate potential usability barriers.

Successful implementation of such software provides measurable benefits, including:

- A reduction in production time through process automation and synchronization of operations;
- Improved accuracy and consistency in process planning and execution;
- Lower operational costs due to optimized resource utilization;
- Enhanced product quality through precise monitoring and data-driven decision-making;
- Greater adaptability to new models, materials, and customer requirements.

For further development, it is recommended to integrate artificial intelligence and data analytics tools to predict production bottlenecks, optimize workflow configurations, and support decision-making processes. Additionally, creating mobile and web-based versions of the interface would provide greater accessibility and real-time control capabilities for managers and production staff.

Overall, the implementation of this software interface marks a step toward the full digital transformation of garment manufacturing enterprises, fostering innovation, sustainability, and competitiveness in the global textile industry.
