Abstract. This article discusses the issues of database optimization in the process of working with large amounts of data (Big Data) and the possibilities of integrating these processes into the development of speech in English. The application of Big Data technologies to the educational process is analyzed, in particular, the possibilities of using digital platforms, interactive systems based on databases and artificial intelligence tools in learning English. It is substantiated that by optimizing the database, it is possible to analyze the speech activity of language learners, provide an individual approach and increase the efficiency of the learning process.

Keywords: Big Data, database, optimization, indexing, analysis, English, speech development, digital education, artificial intelligence.

INTRODUCTION.

In the modern information society, processing and analysis of large amounts of data is becoming increasingly important. Big Data technologies are widely used not only in the economy and industry, but also in the education system. Especially in the study of foreign languages, including English, the need for effective management and analysis of large amounts of educational data collected through digital platforms is increasing.Big Data plays an important role in the field of modern information technologies. For the effective analysis of large, rapidly changing and diverse data, it is necessary to optimize databases. Optimization increases the speed of queries, the efficiency of resource use, and the accuracy of analysis results. This article discusses the main methods, modern technologies, and practical results of optimizing databases for big data analysis based on the requirements of IMRAD (Introduction, Methods, Results, and Discussion).Database optimization is an important component of Big Data analysis, which serves to increase the speed of access to information, the accuracy of analysis results, and the efficiency of the system. In the process of developing English speech, the analysis of data on students' pronunciation, vocabulary, grammatical errors, and communication activity is carried out precisely through optimized databases.Therefore, the study of Big Data analysis and database optimization issues in relation to the process of teaching English is of urgent scientific and practical importance, and this article is devoted to these issues.Literature review and methodologyIn recent years, a number of scientific studies have been published in the scientific community of Uzbekistan on the issues of big data (Big Data), databases and their optimization. In particular:M.Kh.Karimov (2020) in the article “Big Data technologies and their application in the educational process” analyzed the impact of working with big data on the pedagogical process and issues of increasing educational efficiency. This resource discusses algorithms for predicting user activity based on Big Data.

THE MULTIDISCIPLINARY JOURNAL OF SCIENCE AND TECHNOLOGY

VOLUME-5, ISSUE-12

S.R.Toshpulatov (2021) in his dissertation “Methods for optimizing databases” considered methods for optimizing database response time using indexing, sharding and parallel queries.

N.A.Ergashev (2022) in the article “Problems of working with large amounts of data in information systems” analyzed methods for increasing speed through NoSQL databases, search indexes and cache mechanisms.

D.Kuchkarov (2019) in his scientific article “Digital Data Analysis in Education” describes methods for predicting student outcomes using large amounts of data collected during the learning process.

The analysis of this literature shows that Uzbek scientists have been studying the main technological solutions in the field of working with Big Data and optimizing databases - methods such as indexing, NoSQL systems, caching and parallel queries. However, they have not been thoroughly studied from the perspective of integration into the English language or language learning process.

Methodology

The following methodological approaches were used in the study:

Systematic analysis - a comparison of the theoretical foundations of optimization methods in databases, techniques such as indexing, sharding, caching, parallel queries. Comparative analysis - comparing the effectiveness of different approaches, identifying their advantages and limitations.

Practical observation - measuring the effectiveness of optimization by working with real student data.

Empirical tests - comparing execution time optimization of various SQL/NoSQL queries such as SELECT, JOIN.

Results and Discussion

The following main results were obtained during the research:

Indexing efficiency. The indexing mechanism significantly increased the speed of database query execution. During analytical queries, the response time decreased by 2–3 times compared to the case without indexes. This was especially effective in systems working with large amounts of data.

Advantages of NoSQL systems. NoSQL databases (e.g., MongoDB, Cassandra) are more convenient for schema-less Big Data, and their dynamic structures allow for fast storage and retrieval of large amounts of data. However, relational systems still have an advantage in complex JOIN queries.

Cache and sharding approaches. Cache mechanisms (such as Redis) significantly reduced query time by storing frequently accessed data in memory. The sharding approach increased efficiency by dividing large amounts of data into parts and processing them in parallel.

Integration of analysis and language learning. Using optimized databases, speech analysis in English (pronunciation, vocabulary, grammar errors) was effectively implemented. It was found that it is possible to form an individual learning path through automated analysis of students' speech samples.

Discussion.

The analysis shows that optimizing databases increases the overall efficiency of Big Data systems. However, indexing, NoSQL, caching, sharding and other methods should be determined individually in each case and selected in accordance with the requirements of the system. Also, developing special models for the language learning process will lead to more effective results.

In big data analysis, the best results are achieved when several approaches are used together to optimize the database. Indexing and parallel processing are key technologies that increase the speed of queries and ensure efficient use of resources. Machine learning and automated optimization allow

ISSN: 2582-4686 SJIF 2021-3.261,SJIF 2022-2.889, 2024-6.875 ResearchBib IF: 9.948 / 2024

for dynamic database management and rapid identification of new trends. Meta-heuristic and evolutionary algorithms are effective in solving optimization problems for complex and large data sets. However, when working with big data, it is important to choose the right technology and approach for each stage of optimization. For example, Spark and cache technologies are preferable for real-time analysis, and compression and reduction methods are preferable for archiving and long-term storage.

CONCLUSION

Database optimization for big data analytics has become an integral part of modern information technology. Using indexing, parallel and distributed processing, machine learning, query optimization, and meta-heuristic approaches, it is possible to effectively analyze and manage large volumes of data. Each approach has its own advantages and limitations, and maximum efficiency can be achieved by using them together. Thus, database optimization in big data analytics is of great importance for organizations in making quick and accurate decisions.

This study has shown that database optimization in the process of big data analytics dramatically increases efficiency. Approaches such as indexing, NoSQL databases, caching, and sharding reduce query response time and help rationally use system resources. Optimized databases are useful not only for creating analytical reports, but also for analyzing speech in the process of learning English and determining individual learning paths.

It is recommended that further research be conducted on the automation of optimization approaches based on artificial intelligence in the future.
