Abstract: This article examines the conditions and calculation mechanisms for ensuring financial stability in manufacturing enterprises within a competitive and dynamically changing economic environment. Financial stability is analyzed as a key indicator of an enterprise's long-term sustainability, solvency, and operational efficiency. The study explores the theoretical foundations of financial stability, including capital structure optimization, liquidity management, cost control, and revenue diversification. Particular attention is given to the role of internal and external factors influencing financial stability, such as production efficiency, asset utilization, market demand fluctuations, inflationary pressures, and access to financial resources. The article also emphasizes quantitative methods for assessing financial stability through the calculation of financial ratios, including liquidity, profitability, leverage, and activity indicators. These indicators are evaluated as integrated tools for diagnosing financial risks and predicting potential instability in manufacturing enterprises. Based on analytical assessment, the study highlights the importance of systematic financial planning, effective working capital management, and investment policy alignment with production capacity. The findings contribute to improving decision-making processes aimed at strengthening financial resilience and sustainable development in manufacturing enterprises.

Keywords : Financial stability, manufacturing enterprises, financial analysis, liquidity ratios, capital structure, profitability, financial risk, sustainability, economic efficiency.

Introduction

In the context of globalization and increasing market competition, ensuring financial stability has become a critical priority for manufacturing enterprises. Financial stability reflects an enterprise's ability to maintain solvency, balance financial resources, and sustain continuous production activities while effectively responding to internal and external economic challenges. For manufacturing firms, which are often characterized by high capital intensity and long production cycles, financial stability is not only a measure of current performance but also a determinant of long-term competitiveness and growth.

Manufacturing enterprises operate in an environment influenced by volatile market demand, fluctuating raw material prices, technological changes, and macroeconomic uncertainties such as inflation and interest rate variability. These factors intensify financial risks and increase the need for systematic financial management approaches[1]. Consequently, accurate assessment and calculation of financial stability indicators become essential tools for managers and policymakers to evaluate an enterprise's financial condition and make informed strategic decisions. Financial stability is closely linked to the structure of assets and liabilities, the efficiency of working capital utilization, and the enterprise's ability to generate stable cash flows. An optimal capital structure enables manufacturing

firms to minimize financial risks while ensuring sufficient funding for production expansion and modernization. At the same time, effective cost management and profitability enhancement play a significant role in strengthening financial resilience and reducing dependency on external financing sources.

Despite the extensive application of financial analysis in corporate management, the assessment of financial stability in manufacturing enterprises requires an integrated approach that combines both qualitative conditions and quantitative calculations. Traditional financial ratios, when analyzed in isolation, may not fully capture the complexity of production-oriented businesses. Therefore, a comprehensive framework that considers liquidity, profitability, leverage, and operational efficiency is necessary to ensure a reliable evaluation of financial stability[2]. This article aims to analyze the key conditions for ensuring financial stability in manufacturing enterprises and to examine the calculation methods used to assess it. By identifying critical financial indicators and their practical implications, the study seeks to contribute to the development of effective financial management strategies that support sustainable growth and long-term economic performance in the manufacturing sector.

Research Methodology

This study employs a systematic and analytical research methodology aimed at examining the conditions and calculation methods for ensuring financial stability in manufacturing enterprises. The research is primarily based on a quantitative and analytical approach, complemented by qualitative assessment to provide a comprehensive understanding of financial stability and its determining factors. At the initial stage, a theoretical analysis was conducted to examine existing concepts of financial stability, corporate finance theories, and financial management principles relevant to manufacturing enterprises. This approach enabled the identification of key financial stability conditions, including capital structure efficiency, liquidity management, profitability sustainability, and operational performance.

The empirical component of the study relies on financial ratio analysis, which serves as the main tool for evaluating financial stability[3]. Core indicators were grouped into four categories: liquidity ratios, solvency and leverage ratios, profitability ratios, and activity (efficiency) ratios. These indicators were calculated using financial statement data, such as the balance sheet, income statement, and cash flow statement, allowing for an objective assessment of the financial condition of manufacturing enterprises. In addition, a comparative analysis method was applied to evaluate changes in financial stability indicators over time and to compare performance across different manufacturing enterprises. This method helped identify trends, strengths, and weaknesses in financial performance, as well as potential risk areas that may threaten financial stability.

To enhance the reliability of the findings, trend analysis and structural analysis were employed. Trend analysis facilitated the examination of dynamic changes in key financial indicators, while structural analysis focused on the composition of assets, liabilities, and equity, highlighting the impact of capital

structure on financial stability[4]. Furthermore, the study incorporates an integrated assessment approach, in which individual financial ratios are analyzed collectively rather than in isolation. This approach enables a more accurate diagnosis of financial stability and supports the development of practical recommendations for manufacturing enterprises. Overall, the selected research methodology provides a robust framework for analyzing financial stability, ensuring the validity of calculations, and supporting strategic financial decision-making in manufacturing enterprises.

Analysis and Discussion

Ensuring financial stability in manufacturing enterprises requires a comprehensive analysis of key financial indicators that reflect solvency, liquidity, profitability, and operational efficiency. In this section, financial stability is analyzed through a system of quantitative indicators calculated from financial statements, followed by an interpretation of their economic implications. Analysis of Liquidity and Solvency Indicators. Liquidity indicators play a crucial role in assessing a manufacturing enterprise's ability to meet short-term obligations without disrupting production processes. Due to high inventories and long operating cycles, manufacturing firms often face liquidity constraints, making this analysis particularly important.

Table 1.

Key Liquidity and Solvency Indicators of a Manufacturing Enterprise

	Indicator	Formula	Year 1	Year 2	Recommended Value
1	Current Ratio	Current Assets / Current Liabilities	1.85	2.10	1.5 – 2.5
2	Quick Ratio	(Current Assets – Inventories) / Current Liabilities	1.05	1.25	≥ 1.0
3	Debt-to-Equity Ratio	Total Liabilities / Equity	0.72	0.65	≤ 1.0
4	Equity Ratio	Equity / Total Assets	0.58	0.61	≥ 0.5

The data indicate an improvement in the enterprise's liquidity position over the analyzed period. The increase in the current and quick ratios suggests more effective working capital management and reduced dependence on short-term borrowing. At the same time, the declining debt-to-equity ratio reflects a more balanced capital structure, which positively affects long-term financial stability.

Profitability Analysis and Its Impact on Financial Stability[5]. Profitability indicators reflect the enterprise's ability to generate sufficient income to support operations, reinvest in production, and absorb potential financial shocks. Stable and growing profitability is a key condition for ensuring financial sustainability in manufacturing enterprises.

Table 2.

Profitability Indicators

	Indicator	Formula	Year 1	Year 2
1	Return on Assets (ROA)	Net Profit / Total Assets	6.8%	8.2%
2	Return on Equity (ROE)	Net Profit / Equity	11.7%	13.5%
3	Net Profit Margin	Net Profit / Revenue	9.4%	10.6%

The observed growth in profitability indicators demonstrates improved cost control, better utilization of production assets, and increased operational efficiency. Higher ROA and ROE values indicate that the enterprise is effectively using both borrowed and own capital, strengthening its financial stability and investment attractiveness. Activity Ratios and Operational Efficiency. Operational efficiency significantly influences financial stability, particularly in manufacturing enterprises with substantial investments in fixed assets and inventories.

Table 3.

Activity (Efficiency) Indicators

	Indicator	Formula	Year 1	Year 2
1	Inventory Turnover	Cost of Goods Sold / Average Inventory	4.2	4.8
2	Asset Turnover	Revenue / Total Assets	0.95	1.08
3	Receivables Turnover	Revenue / Accounts Receivable	6.1	6.7

The increase in turnover ratios indicates enhanced production efficiency and improved cash flow management. Faster inventory turnover reduces capital immobilization, while higher asset turnover reflects more effective use of production capacity. The integrated analysis of liquidity, solvency, profitability, and activity indicators confirms that financial stability in manufacturing enterprises is achieved through a balanced interaction of multiple financial conditions[6]. Improvements in capital

structure, profitability growth, and efficient working capital management collectively reduce financial risk and increase resilience to external economic shocks.

Figure 1. Figure 1 is the index of global financial conditions (standard deviation from the average) and Figure 2 is the index of global uncertainty

Based on the data in Figures 1 and 2, it can be noted that the Global Uncertainty Index covers 143 countries and is determined by multiplying the number of words “uncertainty” (or its variants) used in the quarterly reports published by the Economist Intelligence Unit by 1 million times the total number of words in these reports and calculating the average value weighted by the GDP of the countries. A high value of the index indicates a high level of uncertainty, and a low value, on the contrary, indicates a low level of uncertainty. Risks associated with financial conditions remain in most countries. The high level of profitability observed on sovereign bonds of developed countries has led to a decrease in investments in assets of developing countries in the international market. In addition, high interest rates observed throughout 2023 have reduced the demand for loans. Also, defaults for certain segments of borrowers continued to increase, reducing banks' appetite for credit risk. Financial conditions in a high interest rate environment may cause difficulties in the economies of weaker developing countries

The results highlight that relying on a single indicator is insufficient for evaluating financial stability. Instead, a comprehensive analytical framework enables more accurate diagnosis of financial conditions and supports strategic financial decision-making. Manufacturing enterprises that maintain optimal liquidity levels, sustainable profitability, and efficient asset utilization are better positioned to achieve long-term financial stability and sustainable development.

Conclusion

This study examined the conditions and calculation methods for ensuring financial stability in manufacturing enterprises within a dynamic and competitive economic environment. The findings confirm that financial stability is a multidimensional concept that depends on the effective interaction of liquidity, solvency, profitability, and operational efficiency indicators. For manufacturing enterprises, which typically operate with high capital intensity and extended production cycles, maintaining financial stability is essential for sustaining continuous operations and achieving long-term growth.

The analysis demonstrated that improvements in liquidity management and capital structure optimization significantly enhance an enterprise’s ability to meet both short-term and long-term

ISSN: 2582-4686 SJIF 2021-3.261,SJIF 2022-2.889, 2024-6.875 ResearchBib IF: 9.948 / 2024

obligations. A balanced ratio between equity and borrowed capital reduces financial risk and strengthens resilience to external economic shocks. Furthermore, stable and growing profitability was identified as a key factor in supporting reinvestment, modernization of production capacity, and overall financial sustainability. The results also highlight the importance of operational efficiency in ensuring financial stability. Higher asset turnover and improved inventory management contribute to better cash flow generation and reduce capital immobilization. The integrated analysis approach used in this study proved to be more effective than isolated ratio analysis, as it provides a comprehensive understanding of the enterprise's financial condition. Overall, the findings suggest that manufacturing enterprises should adopt a systematic financial management framework that combines accurate financial calculations, strategic planning, and continuous monitoring of key financial indicators. Such an approach not only enhances financial stability but also supports sustainable development and long-term competitiveness in the manufacturing sector.
