SPECIFICS OF NURSING CARE FOR PATIENTS IN AN ARTIFICIAL COMA: NURSING APPROACH AND PRACTICAL RECOMMENDATIONS

Irgasheva Raykhon
Surkhandarya Branch of the Republican Scientific Center for Emergency Medical Care

Abstract: This article examines the specific aspects of nursing care for patients in an artificial coma, focusing on the professional role and responsibilities of nurses in the intensive care unit (ICU). It analyzes the peculiarities of patient care during a coma state, including monitoring vital functions, preventing complications, ensuring hygiene, and providing psychological support to the patient's family. The study also presents practical recommendations to improve the quality and effectiveness of nursing care based on research findings and clinical practice.

Keywords: Artificial coma, nursing care, intensive care, patient monitoring, complication prevention, nursing responsibilities.

Relevance of the Topic: Artificial coma is a critical and widely used medical intervention in modern intensive care units. Patients in this state are entirely dependent on external life-support systems and require constant monitoring and professional care. The risk of developing hospital-acquired infections, pressure ulcers, respiratory complications, and muscle atrophy is significantly higher in patients under artificial coma. Therefore, ensuring qualified and comprehensive nursing care is a key factor in the successful recovery and prevention of adverse outcomes in such patients.

Purpose of the Study: The purpose of this study is to analyze the specifics of nursing care for patients in an artificial coma, assess the effectiveness of nursing interventions, and develop practical recommendations for improving nursing care in the ICU.

Materials and Methods: The research was conducted from November 2024 to February 2025 in the Intensive Care Unit of the Termez Regional Multidisciplinary Medical Center. The study involved 20 nursing staff members and 30 patients who were placed in an artificial coma for various medical reasons. The following methods were used:

- Analysis of medical records and nursing documentation;
- Structured interviews and surveys of ICU nurses;
- Direct observation of patient care processes;
- Statistical analysis of the incidence of complications during the coma period.

Research Results: The study revealed the following key results:

1. Among the patients in an artificial coma, the most frequent complications were pressure ulcers (28%), ventilator-associated pneumonia (25%), and urinary tract infections (15%).
2. The nursing staff demonstrated a high level of theoretical knowledge of artificial coma care protocols; however, in 35% of cases, inconsistencies between knowledge and actual practice were identified.
3. Regular repositioning of patients every 2 hours, timely hygiene procedures, and the use of preventive measures significantly reduced the occurrence of complications.
4. Psychological support provided to the patient's family by nurses positively influenced the family's emotional state and cooperation with medical personnel.

Conclusions: The study confirms that nursing care plays a critical role in the management of patients in an artificial coma. The effectiveness of nursing interventions is directly related to the nurse's

professional competence, adherence to care protocols, and proactive approach to preventing possible complications. Regular training of nursing staff, implementation of standardized care procedures, and strengthening communication with the patient's family are essential measures to improve the quality of care for patients in an artificial coma.
