Abstract. Comorbid infections, defined as the simultaneous presence of two or more infectious diseases in a single patient, represent a serious problem in pediatrics. Young children, especially those aged 4 to 10 years, are particularly susceptible to comorbid infections due to their immature immune system, frequent attendance at childcare facilities, and a wide range of pathogens circulating within the population. This study aims to analyze the clinical features and outcomes of comorbid infections in a small group of children aged 4-10 years. The obtained data emphasize the need for a comprehensive approach to the diagnosis and treatment of infections in children with comorbid pathology.

Keywords: comorbidity, infections, children, pediatrics, diagnostics, multi-infections.

Introduction. At the beginning of the coronavirus pandemic (in 2020), children were almost immune to the new virus. Their illness was mild or completely asymptomatic. However, by now, several new SARS-CoV-2 strains have already emerged, and the situation has worsened. As of the end of November 2021, nearly 12,000 COVID-19 deaths among children and adolescents have been recorded worldwide. Comorbid infections represent a combination of several infectious diseases in one patient that can exacerbate each other's course and complicate diagnosis and treatment. In pediatric practice, such cases are not uncommon, especially in the age group from 4 to 10 years, when the child's immune system is still developing and more susceptible to exogenous pathogens.

The **aim** of this study was to identify the clinical and diagnostic features of comorbid infections in young children.

Materials and methods

A retrospective observational study was conducted on 13 children aged 4 to 10 years who were admitted to the infectious diseases department of the city children's hospital in 2024. The sample included patients diagnosed with combined infections, confirmed by laboratory testing. The analysis encompassed clinical presentation, laboratory test results (complete blood count, urinalysis, serological and PCR tests), as well as medical history data. The study group consisted of 7 boys and 6 girls. The average age was 6.8 years. Gender distribution: 7 boys (53.8%) and 6 girls (46.2%).

Results

Below is a table showing the distribution of comorbid infection types and their main clinical manifestations:

VOLUME-5, ISSUE-4

Table 1. Characteristics of comorbid infections and clinical symptoms in the examined children (n=13)

No.	Combination of infections	Number of cases	Main symptoms
1	ARVI + intestinal infection	6 (46.2%)	Fever, vomiting, diarrhea, weakness
2	Tonsillitis (streptococcal) + herpes infection	3 (23.1%)	Sore throat, mucosal rashes, high fever
3	Chickenpox + pyoderma	2 (15.4%)	Skin rashes, suppuration of lesions, itching
4	EBV infection + mycoplasma infection	2 (15.4%)	Lymphadenopathy, fever, cough, pharyngitis

The most frequent symptoms were: fever (100%), cough (84.6%), runny nose (69.2%), sore throat (53.8%), diarrhea (30.8%), vomiting (23.1%). In patients with concomitant bacterial infection, signs of intoxication and more pronounced symptoms were observed.

Treatment: All patients received symptomatic therapy (antipyretics, rehydration). In cases of bacterial infection, antibiotic therapy was prescribed in accordance with clinical guidelines. In severe cases, oxygen support was required.

Outcomes: 12 patients (92.3%) achieved full recovery. One patient (7.7%) developed complications in the form of pneumonia, necessitating a longer course of antibiotic therapy and monitoring. The average duration of hospitalization was 5.2 days (range: 3-8 days).

Discussion

The obtained data confirm that in children with comorbid infections, more pronounced clinical symptoms, increased risk of complications, and the need for a comprehensive approach to therapy are observed. The frequent combination of respiratory and gastrointestinal symptoms requires additional diagnostic measures for concomitant pathogens.

To optimize the management of patients with comorbid infections, it is necessary to improve diagnostic algorithms that allow for prompt identification of all present pathogens. In particular, it is advisable to introduce multiplex PCR tests capable of simultaneously detecting a wide range of respiratory viruses and bacteria. This will help avoid unjustified prescription of antibiotics for viral infections and enable timely initiation of antibacterial therapy for bacterial complications.

A promising direction is the study of the role of immunomodulatory therapy in the complex treatment of comorbid infections. Some studies show that the use of immunomodulators can contribute to faster recovery and reduce the risk of complications. However, additional clinical studies are necessary to determine the optimal regimens and dosages of immunomodulatory drugs in children.

An equally important aspect is the prevention of comorbid infections. Vaccination against

common infectious diseases such as influenza, pneumococcal infection, and chickenpox can significantly reduce the risk of comorbidity. It is also necessary to observe personal hygiene measures, such as regular hand washing and use of antiseptics, especially during seasonal increases in morbidity.

Further research in the field of comorbid infections in children should focus on identifying risk factors, developing prognostic models, and optimizing treatment approaches. Interdisciplinary collaboration among pediatricians, infectious disease specialists, immunologists, and microbiologists will enhance the quality of medical care for children with comorbid infections and reduce the burden of these diseases.

Conclusion

Comorbid infections in young children are a common and clinically significant problem that requires early diagnosis, a multidisciplinary approach, and individualized therapy. Detecting hidden infections during the typical course of the primary disease allows for improved treatment effectiveness and reduced risk of complications.
